

Finite Fields

From now on, we look only at channels whose input and output alphabets are the same, each consisting of the elements of some *finite field*.

A finite field consists of a finite collection of “numbers” that behave like real and complex numbers. Specifically,

- Addition and multiplication are defined, and they are commutative and associative, and multiplication is distributive over addition.
- There are numbers called 0 and 1, such that $a + 0 = a$ and $a \cdot 1 = a$ for all a .
- Subtraction and division (except by 0) can be done, and these operations are the inverses of addition and multiplication.

The Finite Field F_2

The smallest finite field, called F_2 or $GF(2)$, has just two elements, 0 and 1. Addition and multiplication are defined as follows:

$$\begin{array}{ll} 0 + 0 = 0 & 0 \cdot 0 = 0 \\ 0 + 1 = 1 & 0 \cdot 1 = 0 \\ 1 + 0 = 1 & 1 \cdot 0 = 0 \\ 1 + 1 = 0 & 1 \cdot 1 = 1 \end{array}$$

This can also be seen as arithmetic modulo 2 (called \mathbb{Z}_2).

Viewed as logical operations, addition is the same as ‘exclusive-or’, and multiplication is the same as ‘and’.

Note: In F_2 , $-a = a$, and hence $a - b = a + b$.

Other Finite Fields

There is a finite field with p elements for every prime p . This field is the same as \mathbb{Z}_p , in which arithmetic on $0, \dots, p-1$ is done module p .

For example, $\mathbb{Z}_3 = F_3$ works as follows:

$$\begin{array}{ll} 0 + 0 = 0 & 0 \cdot 0 = 0 \\ 0 + 1 = 1 & 0 \cdot 1 = 0 \\ 0 + 2 = 2 & 0 \cdot 2 = 0 \\ 1 + 0 = 1 & 1 \cdot 0 = 0 \\ 1 + 1 = 2 & 1 \cdot 1 = 1 \\ 1 + 2 = 0 & 1 \cdot 2 = 2 \\ 2 + 0 = 2 & 2 \cdot 0 = 0 \\ 2 + 1 = 0 & 2 \cdot 1 = 2 \\ 2 + 2 = 1 & 2 \cdot 2 = 1 \end{array}$$

There’s also a finite field for every integer power of a prime, with p^e elements. These fields are *not* the same as \mathbb{Z}_{p^e} , which is not a field when $e > 1$. (See J&J, Section 6.1.)

Vector Spaces Over a Finite Field

Just as we can define vectors over real numbers, we can define vectors over a finite field. We get to add such vectors, and multiply them by a scalar from the finite field.

We can think of these vectors as n -tuples of field elements. For instance, with vectors of length five over F_2 :

$$\begin{aligned} (1, 0, 0, 1, 1) + (0, 1, 0, 0, 1) &= (1, 1, 0, 1, 0) \\ 1 \cdot (1, 0, 0, 1, 1) &= (1, 0, 0, 1, 1) \\ 0 \cdot (1, 0, 0, 1, 1) &= (0, 0, 0, 0, 0) \end{aligned}$$

Most properties of real vector spaces continue to hold — eg, the existence of basis vectors.

We refer to the vector space of all n -tuples from F_q as F_q^n . We will use boldface letters such as \mathbf{u} and \mathbf{v} to refer such vectors.

Linear Codes

We can view F_q^n as the input and output alphabet of the n th extension of a channel with input and output alphabet F_q .

A code, \mathcal{C} , for this extension of the channel is a subset of F_q^n .

\mathcal{C} is a *linear code* if the following conditions hold:

- 1) If \mathbf{u} and \mathbf{v} are codewords of \mathcal{C} , then $\mathbf{u} + \mathbf{v}$ is also a codeword of \mathcal{C} .
- 2) If \mathbf{u} is a codeword of \mathcal{C} and a is in F_q , then $a\mathbf{u}$ is also a codeword of \mathcal{C} .

In other words, \mathcal{C} must be a subspace of F_q^n . Note that the all-zero codeword must be in \mathcal{C} , since $\mathbf{0} = 0\mathbf{u}$ for any \mathbf{u} .

Note: For binary codes (over F_2), condition (2) will always hold if condition (1) does, since $1\mathbf{u} = \mathbf{u}$ and $0\mathbf{u} = \mathbf{0} = \mathbf{u} + \mathbf{u}$.

Linear Codes From Basis Vectors

We can construct a linear code by choosing k linearly-independent *basis vectors* from F_q^n .

We'll call the basis vectors $\mathbf{u}_1, \dots, \mathbf{u}_k$. We define the set of codewords to be all those vectors that can be written in the form

$$a_1\mathbf{u}_1 + a_2\mathbf{u}_2 + \dots + a_k\mathbf{u}_k$$

where a_1, \dots, a_k are elements of F_q .

The codewords obtained with different a_1, \dots, a_k are all different. (Otherwise $\mathbf{u}_1, \dots, \mathbf{u}_k$ wouldn't be linearly-independent.)

There are therefore q^k codewords.

We can encode a block consisting of k symbols, a_1, \dots, a_k , from F_q as a codeword of length n using the formula above.

This is referred to as an $[n, k]$ code.

Linear Codes From Linear Equations

Another way to define a linear code for F_q^n is to provide a set of simultaneous equations that must be satisfied for \mathbf{v} to be a codeword.

These equations have the form $\mathbf{b} \cdot \mathbf{v} = 0$, ie

$$b_1v_1 + b_2v_2 + \dots + b_nv_n = 0$$

The set of solutions is a linear code because

- 1) $\mathbf{b} \cdot \mathbf{u} = 0$ and $\mathbf{b} \cdot \mathbf{v} = 0$ implies $\mathbf{b} \cdot (\mathbf{u} + \mathbf{v}) = 0$.
- 2) $\mathbf{b} \cdot \mathbf{v} = 0$ implies $\mathbf{b} \cdot (a\mathbf{v}) = 0$.

If we have $n - k$ such equations, and they are independent, the code will have q^k codewords.

A $[3, 1]$ Code Over F_3

As a simple example, consider the code for F_3^3 defined by the following equations that must be satisfied by a codeword \mathbf{v} :

$$v_1 + v_2 = 0$$

$$v_2 + 2v_3 = 0$$

There should be three codewords in this code.

One of them is $(1, 2, 2)$, since in F_3 (which is \mathbb{Z}_3), $1 + 2 = 0$ and $2 + 2 \cdot 2 = 2 + 1 = 0$.

We can take this codeword as a basis vector, and find the other two codewords as the multiples of it:

$$0(1, 2, 2) = (0, 0, 0), \quad 2(1, 2, 2) = (2, 1, 1)$$

The Repetition Codes Over F_2

A repetition code over F_2^n has only two codewords — one has all 0s, the other all 1s.

This is a linear $[n, 1]$ code, with $(1, \dots, 1)$ as the basis vector.

The code is also defined by the following $n - 1$ equations satisfied by a codeword \mathbf{v} :

$$v_1 + v_2 = 0, \quad v_2 + v_3 = 0, \quad \dots, \quad v_{n-1} + v_n = 0$$

The Single Parity-Check Codes

An $[n, n - 1]$ code over F_2 can be defined by the following single equation satisfied by a codeword \mathbf{v} :

$$v_1 + v_2 + \dots + v_n = 0$$

In other words, the *parity* of all the bits in a codeword must be even.

This code can also be defined using $n - 1$ basis vectors. One choice of basis vectors when $n = 5$ is as follows:

$$\begin{aligned} (1, 0, 0, 0, 1) \\ (0, 1, 0, 0, 1) \\ (0, 0, 1, 0, 1) \\ (0, 0, 0, 1, 1) \end{aligned}$$

A $[5, 2]$ Binary Code

Recall the following code from lecture 9b:

$$\{ 00000, 00111, 11001, 11110 \}$$

Is this a linear code? We need to check that all sums of codewords are also codewords:

$$00111 + 11001 = 11110$$

$$00111 + 11110 = 11001$$

$$11001 + 11110 = 00111$$

We can generate this code using 00111 and 11001 as basis vectors. We then get the four codewords as follows:

$$0 \cdot 00111 + 0 \cdot 11001 = 00000$$

$$0 \cdot 00111 + 1 \cdot 11001 = 11001$$

$$1 \cdot 00111 + 0 \cdot 11001 = 00111$$

$$1 \cdot 00111 + 1 \cdot 11001 = 11110$$

The $[7, 4]$ Binary Hamming code

The $[7, 4]$ Hamming code is defined over F_2 by the following equations that are satisfied by a codeword \mathbf{u} :

$$u_4 + u_5 + u_6 + u_7 = 0$$

$$u_2 + u_3 + u_6 + u_7 = 0$$

$$u_1 + u_3 + u_5 + u_7 = 0$$

Since these equations are independent, there should be 16 codewords.

We can also define the code in terms of the following four basis vectors:

$$1001100, 0101010, 1110000, 1101001$$

We will see later that this code is capable of correcting any single error.
