

Agenda

- Oracle10g: Oracle's first generation of self-managing database
- Oracle's Approach to Self-managing
- Oracle10g Manageability Foundation
- Automatic Database Diagnostic Monitor (ADDM)

- Self-managing Components
- Conclusion and Future Directions

- Oracle10g is the latest version of the Oracle DBMS, released early 2004
- One of the main focus of that release was selfmanagement
 - Effort initiated in Oracle9i
- Our vision when we started this venture four years ago: make Oracle fully self-manageable
- We believe Oracle10g is a giant step toward this goal

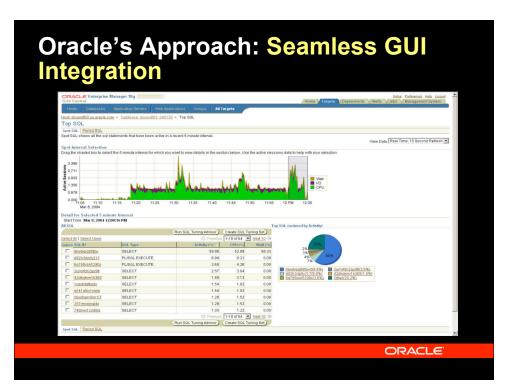

Oracle's Approach: Server Resident

Technology built inside the database server

- Eliminate management problems rather than "hiding" them behind a tool
- Minimize Performance Impact
- Act "Just in Time" (e.g. push versus pull)
- Leverage existing technology
- Effective solutions require complete integration with various server components
 - server becoming so sophisticated that a tool based solution can no longer be truly effective

ORACLE

Mandatory if the end-goal is to build a truly <u>self-managing</u> database server

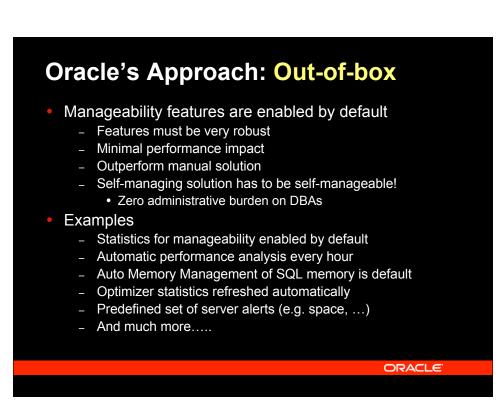

Oracle's Approach: Holistic

- Avoid a collection of point solutions
- Instead, build a comprehensive solution
 - Core manageability infrastructure
 - Comprehensive statistics component
 - · Workload Repository
 - · Server based alerts
 - Advisory framework
 - Central self-diagnostic engine built into core database (Automatic Database Diagnostic Monitor or ADDM)
 - Self-managing Components
 - Auto Memory Management, Automatic SQL Tuning, Automatic Storage Management, Access Advisor, Auto Undo Retention, Space Alerts, Flashback....

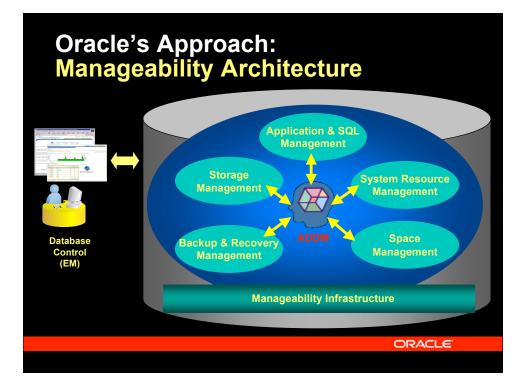

ORACLE

 Follow the self-managing loop: Observe, Diagnose, Resolve

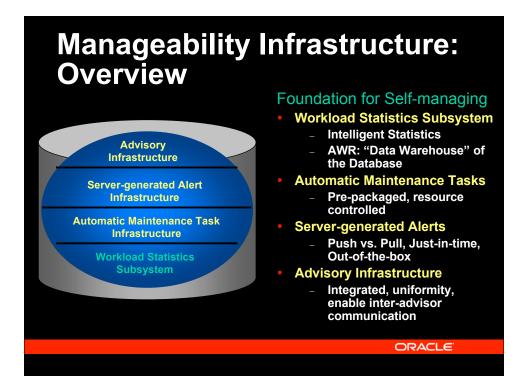

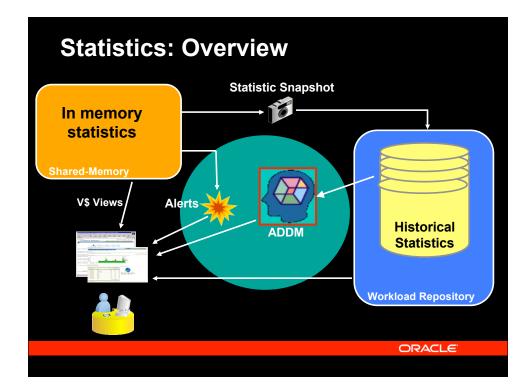

Oracle's Approach: Manageability for All

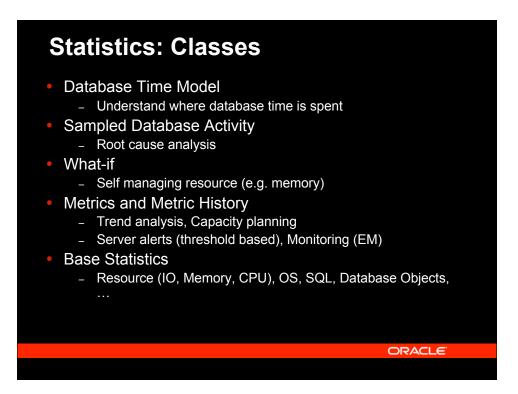

- Low End Customers
 - No dedicated administrative staff
 - Automated day to day operations
 - → Optimal performance out of the box, no need to set configuration parameters
- High End Customers
 - Flexibility to adapt product to their needs
 - Self-management features should outperform manual tuning and ensure predictable behavior
 - Need to understand and monitor functioning of self-management operations
 - → Help DBAs in making administrative decisions (no need for DBA to be rocket scientist!)
- Any workload: OLTP, DSS, mixed

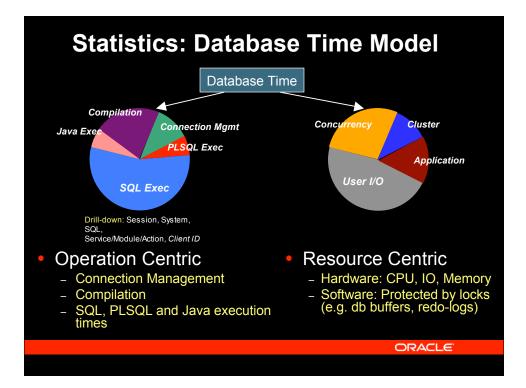

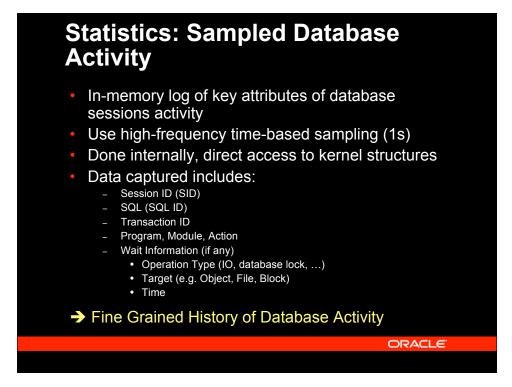

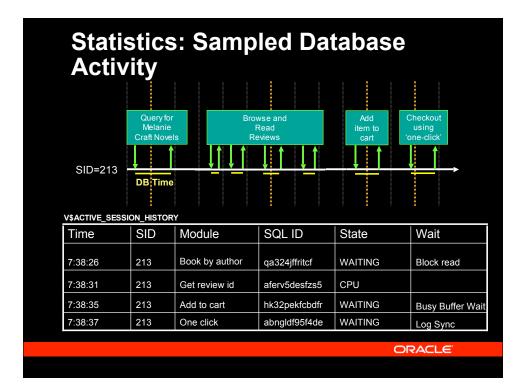

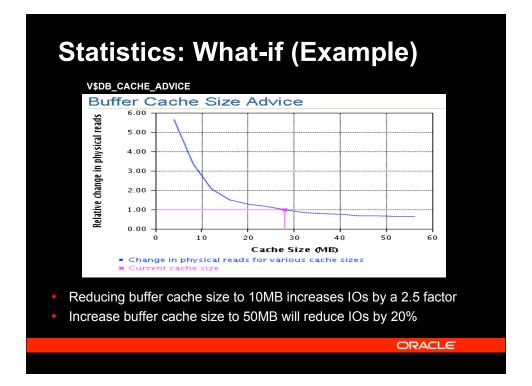

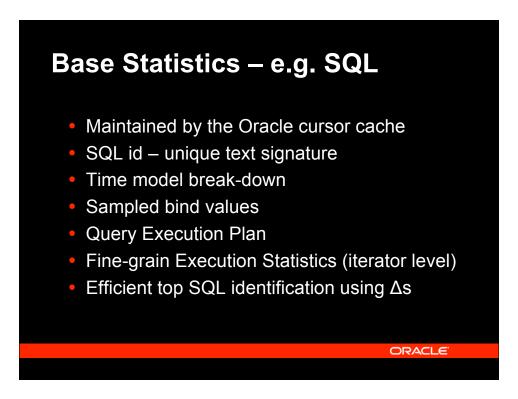

Statistics: What-if (Overview)

- Predict performance impact of changes in amount of memory allotted to a component, both decrease and increase.
- Highly accurate, maintained automatically by each memory component based on workload.
- Use to diagnose under memory configuration (ADDM).
- Use to decide when to transfer memory between shared-memory pools (Auto Memory Management).
- Not limited to memory (e.g. use to compute auto value of MTTR)
- Produced by
 - Buffer cache
 - Shared pool integrated cache for both database object metadata and SQL statements
 - Java cache for class metadata
 - SQL memory management private memory use for sort, hash-joins, bitmap operators

AWR: Automatic Workload Repository

- Self-Managing Repository of Database Workload Statistics
 - Periodic snapshots of in-memory statistics stored in database
 - Coordinated data collection across cluster nodes
 - Automatically purge old data using time-based partitioned tables
 - Out-Of-The-Box: 7 days of data, 1-hour snapshots
- Content and Services
 - Time model, Sampled DB Activity, Top SQL, Top objects, ...
 - SQL Tuning Sets to manage SQL Workloads
- Consumers
 - ADDM, Database Advisors (SQL Tuning, Space, ...), ...
 - Historical performance analysis

ADDM: Motivation

Problem: Performance tuning requires high-expertise and is most time consuming task

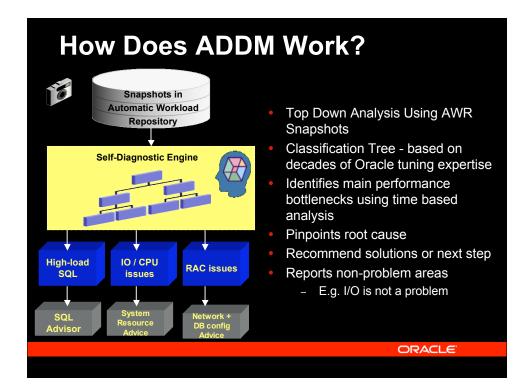

- Performance and Workload Data Capture
 - System Statistics, Wait Information, SQL Statistics, etc.
- Analysis
 - What types of operations database is spending most time on?
 - Which resources is the database bottlenecked on?
 - What is causing these bottlenecks?
 - What can be done to resolve the problem?
- Problem Resolution
 - If multiple problems identified, which is most critical?
 - How much performance gain I expect if I implement this solution?

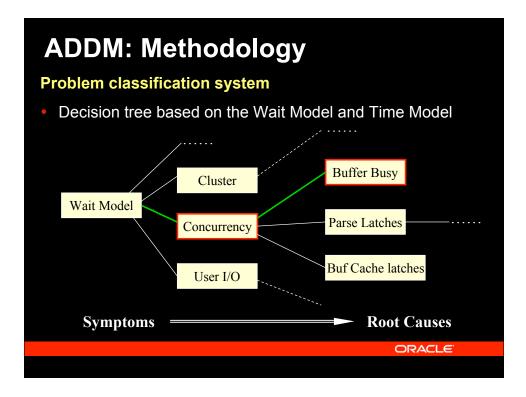

ORACLE

ADDM: Overview

- Diagnose component of the system wide self-managing loop
- ... and the entry point of the resolve phase
- Central Management Engine
 - Integrate all components together
 - Holistic time based analysis
 - Throughput centric top-down approach
 - Distinguish symptoms from causes (i.e root cause analysis)
- Runs proactively out of the box (once every hour)
 - Result of each analysis is kept in the workload repository
- Can be used reactively when required

→ ADDM is the system-wide optimizer of the database

ADDM: Taxonomy of Findings

Hardware Resource Issues

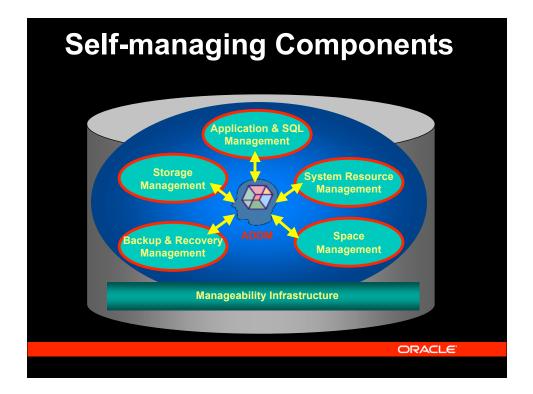

- CPU (capacity, top-sql, ...)
- IOs (capacity, top-sql, top-objects, undersized memory cache)
- Cluster Interconnect
- Memory (OS paging)
- Software Resource Issues
 - Application locks
 - Internal contention (e.g. access to db buffers)
 - Database Configuration
- Application Issues
 - Connection management
 - Cursor management (parsing, fetching, ...)

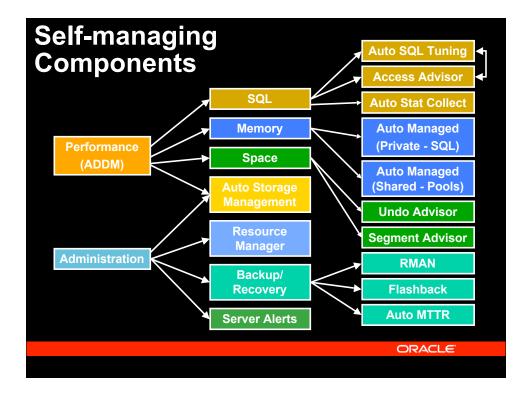

ORACLE

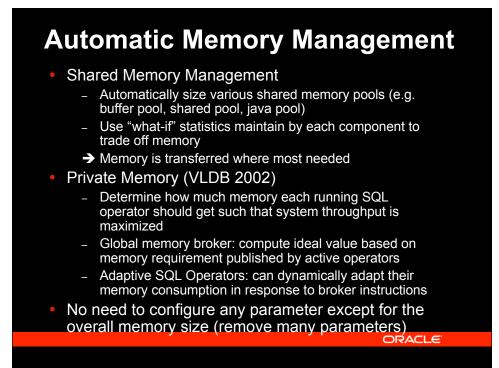

ORACLE

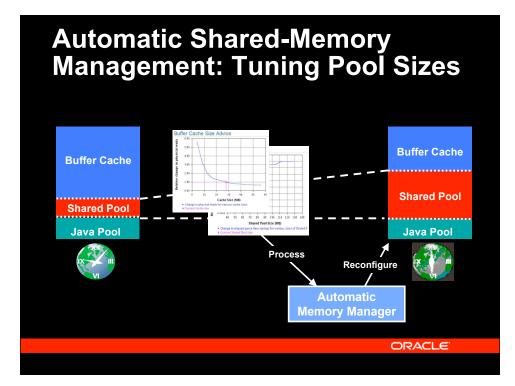

ADDM: Real-world Example

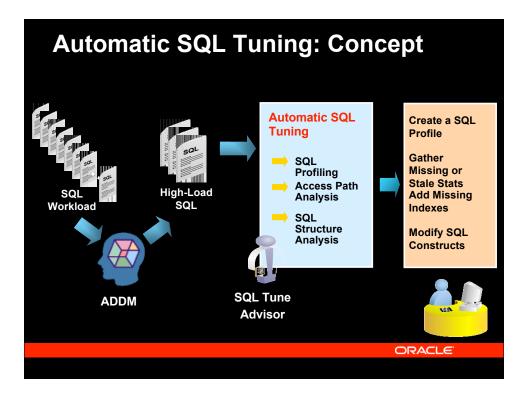

- Reported by Qualcomm when upgrading to Oracle10g
- After upgrading, Qualcomm noticed severe performance degradation
- Looked at last ADDM report
- ADDM was reporting high-cpu consumption
 and identified the root cause: a SQL statement
- ADDM recommendation was to tune this statement using Automatic SQL tuning
- Automatic SQL tuning identified missing index. The index was created and performance issue was solved
- In this particular case, index was dropped by accident during the upgrade process!

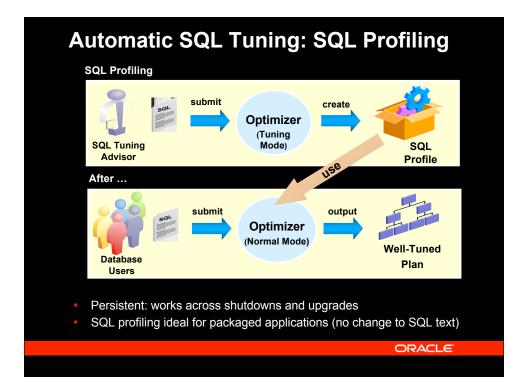

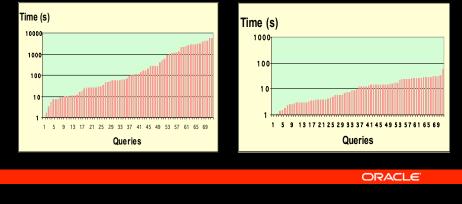

Automatic SQL Tuning: Overview

- Performed by the Oracle query optimizer running in tuning mode
 - Uses same plan generation process but performs additional steps that require lot more time
- Optimizer uses this extra time to
 - Profile the SQL statement
 - Validate data statistics and its own estimate using dynamic sampling and partial executions
 - Look at past executions to determine best optimizer settings
 - Optimizer corrections and settings are stored in a new database object, named a "SQL Profile"
 - Explore plans which are outside its regular search space
 - Ÿ To investigate the use of new access structures (i.e. indexes)
 - Ÿ To investigate how SQL restructuring would improve the plan

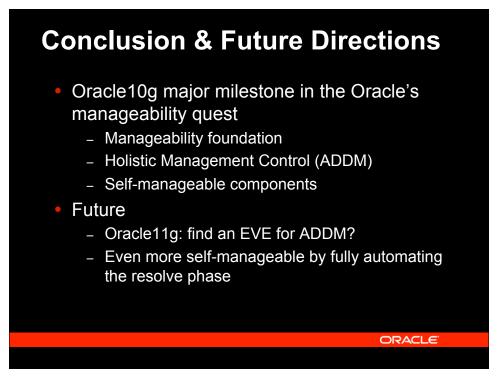

SQL Profiling: Performance Evaluation Using 73 high-load queries from GFK, a market analysis company located in Germany Before... ...After

Automatic SQL Tuning: What-if Analysis

- Schema changes: invokes access advisor
 - Comprehensive index solutions (b-tree, bitmap, functional)
 - Materialized views recommendations maximizing query rewrite while minimizing maintenance cost
 - Any combination of the above two (e.g. new MV with an index on it)
 - Consider the entire SQL workload
- SQL Structure Analysis
 - Help apps developers to identify badly written statements
 - Suggest restructuring for efficiency by analyzing execution plan
 - Solution requires changes in SQL semantic → different from optimizer automatic rewrite and transformation
 - Problem category
 - Semantic changes of SQL operators (NOT IN versus NOT EXISTS)
 - Syntactic change to predicates on index column (e.g. remove type mismatch to enable index usage)
 - SQL design (add missing join predicates)
