Architectures and Algorithms for Internet-Scale (P2P) Data Management

Joe Hellerstein Intel Research & UC Berkeley

## Powerpoint Compatibility Note

This file was generated using MS PowerPoint 2004 for Mac. It may not display correctly in other versions of PowerPoint. In particular, animations are often a problem.

### Overview

## What, Why The Platform

- Ongoing Research Structured Overlays: DHTs Query Processing on OverlaysStorage Models & Systems
  - Security and Trust

  - Tools and Platforms - Closing thoughts
- Client-Server
  Floodsast
- Hierarchies

Network Data Independence

A Little Gossip
 Commercial Offerings
 Lessons and Limitations

## Acknowledgments

### Outline

- Internet-Scale systems
- Some guiding applications

### Scoping the Tutorial

- Architectures and Algorithms for Data Management
  The perils of overviews
- Can't cover everything. So much here!
- Some interesting things we'll skip

   Semantic Mediation: data integration on steroids
   E.g., Hyperion (Toronto), Piazza (UWash), etc.
  - High-Throughput ComputingI.e. The Grid

  - Complex data analysis/reduction/mining
     E.g. p2p distributed inference, wavelets, regression, matrix computations, etc.

### Moving Past the "P2P" Moniker: The Platform

- The "P2P" name has lots of connotations
   Simple filestealing systems

  - Very end-user-centric
- - Many participating machines, symmetric in function
  - Very Large Scale (MegaNodes, not PetaBytes)
- Minimal (or non-existent) management
- Note: user model is flexible
  - Could be embedded (e.g. in OS, HW, firewall, etc.) • Large-scale hosted services a la Akamai or Google – A key to achieving "autonomic computing"?

### **Overlay Networks**

- P2P applications need to:

   Track identities & (IP) addresses of peers
   May be many!
   May have significant Churn
   Best not to have n<sup>2</sup> ID references
   Route messages among peers
   If you don't keep track of all peers, this is "multi-hop"
- Peers are doing both naming and routing
  IP becomes "just" the low-level transport

  All the IP routing is opaque

  Control over naming and routing is powerful

  And as we'll see, brings networks into the database era

### Many New Challenges

- - Partial failure
  - Churn
  - Few guarantees on transport, storage, etc.
    Huge optimization space

  - Network bottlenecks & other resource constraints
  - No administrative organizations
  - Trust issues: security, privacy, incentives

• Relative to IP networking – Much higher function, more flexible – Much less controllable/predictable

## Why Bother? Not the Gold Standard

- Hard to beat hosted/managed services

  - p2p Google appears to be infeasible [Li, et al. IPTPS 03]
- Most Resilient? Hmmmm.
   In principle more resistant to DoS attacks, etc.
  - Today, still hard to beat hosted/managed services
    - Geographically replicated, hugely provisioned
    - People who "do it for dollars" today don't do it p2p

### Why Bother II: Positive Lessons from Filestealing

- Vs. the top few killer services -- no VCs required!
- Can afford to "place more bets", try wacky ideas
- Tracking users is trivial
- Provider is liable (for misuse, for downtime, for local laws, etc.)
- Need to pay off startup & maintenance expenses
- Need to protect against liability
- Business requirements drive to particular short-term goals

### Why Bother III? Intellectual motivation

- - Great community of researchers have gathered - Algorithms, Networking, Distributed Systems,
  - Databases - Healthy set of publication venues

  - IPTPS workshop as a catalyst
     Surprising degree of collaboration across areas In part supported by NSF Large ITR (project IRIS)
     UC Berkeley, ICSI, MIT, NYU, and Rice

### Infecting the Network, Peer-to-Peer

- The Internet is hard to change.
  But Overlay Nets are easy!

  P2P is a wonderful "host" for infecting network designs
  - The "next" Internet is likely to be very different
    "Naming" is a key design issue today
    Querying and data independence key tomorrow?
- The Internet was originally an overlay on the telephone network
- There is no money to be made in the bit-shipping business
- A modest goal for DB research: Don't query the Internet.

*Be* the Internet.

- A modest goal for DB research: Don't query the Internet.

### Some Guiding Applications

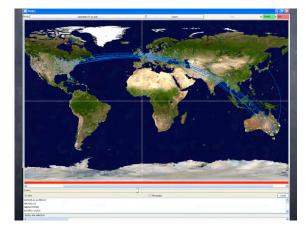

• 0

- Intel Research & UC Berkeley
- LOCKSS
- Stanford, HP Labs, Sun, Harvard, Intel ResearchLiberationWare

### $\varphi$ : Public Health for the Internet

- Security tools focused on "medicine"
   Vaccines for Viruses
- Improving the world one patient at a time
- Weakness/opportunity in the "Public Health" arena
   Public Health: population-focused, community-oriented
   Epidemiology: incidence, distribution, and control in a population
- *Q*: A New Approach
- Perform population-wide measurement
- Enable massive sharing of data and query results
- The "Internet Screensaver"
   Engage end users: education and prevention
- Understand risky behaviors, at-risk populations.
- Prototype running over PIER

## arphi Vision: Network Oracle

- Answering questions about current Internet state
- - Etc.

## LOCKSS: Lots Of Copies Keep Stuff Safe

- Digital Preservation of Academic MaterialsLibrarians are scared with good reason
- Access depends on the fate of the publisher
   Time is unkind to bits after decades
   Plenty of enemies (ideologies, governments, corporations)

### LOCKSS Approach

- Very low-cost hardware, operation and administration
- No central control

- Respect for access controls

- A long-term horizon
- Must anticipate and degrade gracefully with Undetected bit rot

  - Sustained attacks • Esp. Stealth modification
- Solution:
  - P2P auditing and repair system for replicated docs

## LiberationWare

- Take your favorite Internet application
   Web hosting, search, IM, filesharing, VoIP, email, etc.
   Consider using centralized versions in a country with a

  - repressive government
     Trackability and liability will prevent this being used for free speech
- speech
   Now consider p2p
   Enhanced with appropriate security/privacy protections
   Could be the medium of the next Tom Paines
   Examples: FreeNet, Publius, FreeHaven
   p2p storage to avoid censorship & guarantee privacy
   DVI security distance

  - PKI-encrypted storage
  - Mix-net privacy-preserving routing

SIGMOD Record, Sep. 2003

## Recall Codd's Data Independence

- Decouple app-level API from data organization
  - Can make changes to data layout without modifying applications
  - Simple version: location-independent names
  - Fancier: declarative queries

"As clear a paradigm shift as we can hope to find in computer science" - C. Papadimitriou

## The Pillars of Data Independence

<ul> <li>Indexes         <ul> <li>Value-based lookups have</li> </ul> </li> </ul>	DBMS B-Tree
to compete with direct access — Must adapt to shifting data distributions	
<ul> <li>Must guarantee performance</li> </ul>	
Query Optimization     Support declarative queries beyond lookup/search     Must adapt to shifting data distributions     Must adapt to changes in environment	Join Ordering, AM Selection, etc.

### Generalizing Data Independence

- A classic "level of indirection" scheme
   Indexes are exactly that
   Complex queries are a richer indirection
- The key for data independent It's all about *rates of change*
- Hellerstein's Data Independence Inequality:
   Data independence matters when

d(environment)/dt >> d(app)/dt

## Data Independence in Networks

### d(environment)/dt >> d(app)/dt

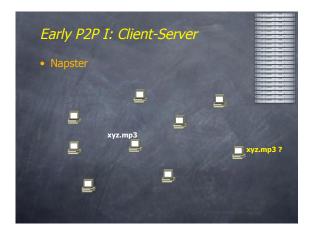

- In databases, the RHS is unusually small This drove the relational database revolution
- In extreme networked systems, LHS is unusually high
   And the applications increasingly complex and data-driven
   Simple indirections (e.g. local lookaside tables) insufficient

## The Pillars of Data Independence

	DBMS	P2P
Value-based lookups have to compete with direct access     Must adapt to shifting data distributions     Must guarantee performance	B-Tree	Content- Addressable Overlay Networks (DHTs)
Query Optimization           - Support declarative queries beyond lookup/search           - Must adapt to shifting data distributions           - Must adapt to changes in environment	Join Ordering, AM Selection, etc.	Multiquery dataflow sharing?

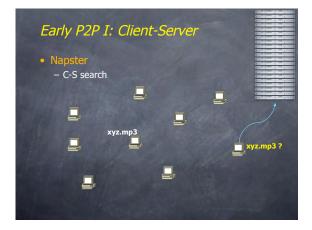

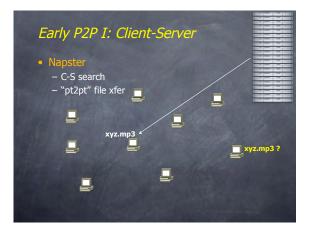

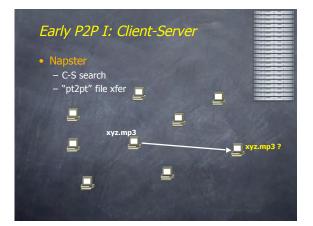

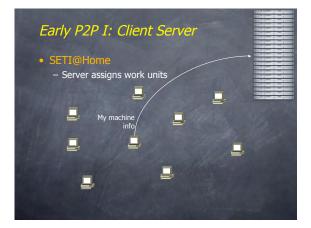

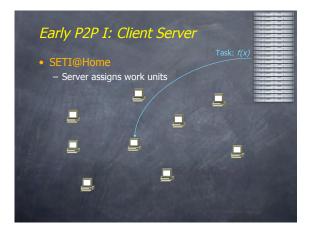

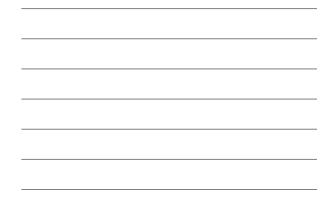

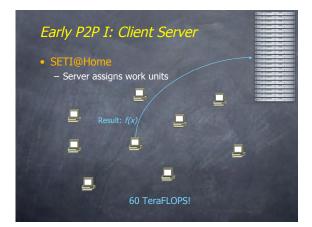

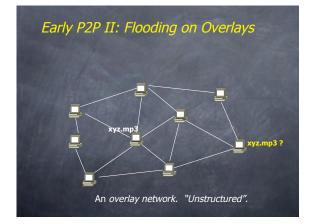

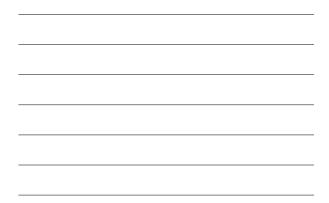

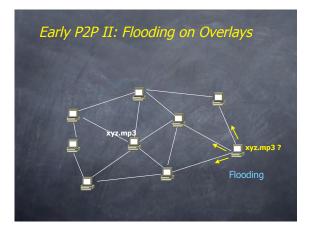

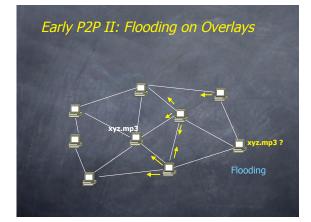

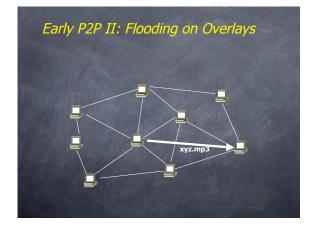

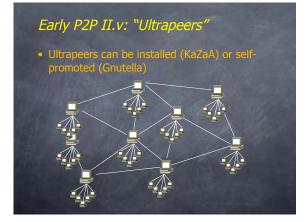

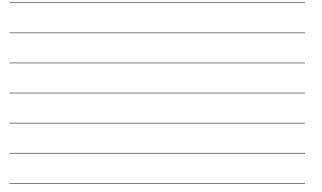

## Hierarchical Networks (& Queries)

- - Hierarchical name space (www.vldb.org, 141.12.12.51) Hierarchical routing Autonomous Systems correlate with name space (though not perfectly) Astrolable [Birman, et al. TOCS 03] OLAP-style aggregate queries down the IP hierarchy
- Hierarchical name space ("clients" + hierarchy of servers) Hierarchical routing w/aggressive caching 13 managed "root servers" IrisNet [Deshande, et al. StorMoD 03] Xpath queries over (selected) DNS (sub)-trees.
- Traditional pros/cons of Hierarchical data mgmt Works well for things aligned with the hierarchy Esp. physical locality a la Astrolabe Inflexible No data independence! Traditional pro

### Commercial Offerings

- - Java/XML Framework for p2p applications
     Name resolution and routing is done with floods & superpeers
     Can always add your own if you like
- - An unstructured overlay, flooded publication and caching
     "does not yet support distributed searches"
- Authentication via signatures (assumes a trusted authority)
   Encryption of traffic
- Groove

   Platform for p2p "experience". IM and asynch collab tools.
   Client-serverish name resolution, backup services, etc.

### Lessons and Limitations

- Client-Server performs well

   But not always feasible
   Ideal performance is often not the key issuel
   Inings that flood-based systems do well
   Organic scaling
   Decentralization of visibility and liability
   Finding popular stuff
   Fancy *local* queries

   Things that flood-based systems do poorl
   Einding uppopular stuff floor stal/URB (d)
- Thi Things that flood-based systems do poorly – Finding unpopular stuff [Loo, et al VLDB 04]
- Fancy *distributed* queries
- Vulnerabilities: data poisoning, tracking, etc.Guarantees about anything (answer quality, privacy, etc.)

### Gossip Protocols (Epidemic Algorithms)

- Originally targeted at database replication towers on the second second
- Point-to-point routing [Vahdat/Becker TR, '00]
   Rumor-mongering of queries instead of flooding [Haas, et al Infocom '02]

- Usually of two forms: What is the "tipping point" where an epidemic infects the whole population? (Percolation theory) What is the expected # of messages for infection?
- A Cornell specialty
   Demers, Kleinberg, Gehrke, Halpern, ...

### DHT Outline

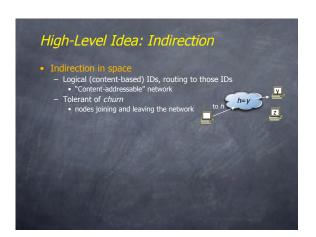

- High-level overview
   Fundamentals of structured network topologies

   And examples
- And examples
  One concrete DHT

  Chord

  Some systems issues

  Storage models & soft state
  Locality
  Churn management

## High-Level Idea: Indirection

- Indirection in time
   Want some scheme to temporally decouple send and receive
   Persistence required. Typical Internet solution: soft state
   Combo of persistence via *storage* and via *retry* 
   "Publisher" requests TL on storage
   Republishes as needed
- Metaphor: Distributed Hash Table

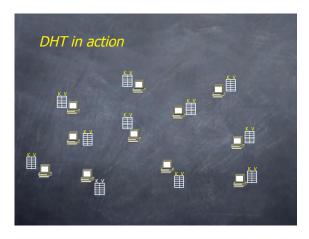

## What is a DHT?

- Hash Table
   data structure that maps "keys" to "values"
   essential building block in software systems
- Distributed Hash Table (DHT) similar, but spread across the Internet

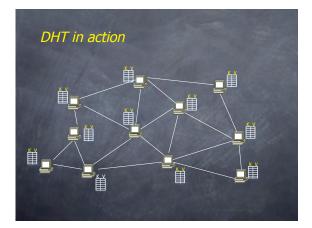

## Interface – insert(key, value) – lookup(key)

### How?

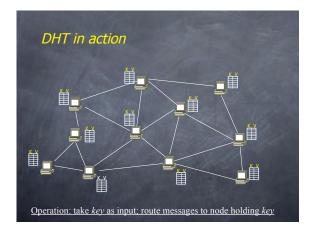

- - Given key as input; route messages toward node holding key

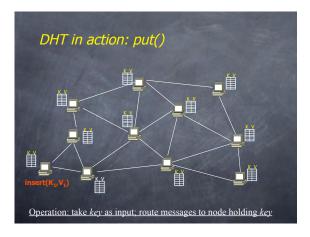

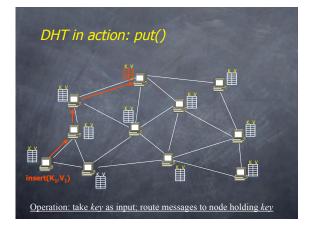

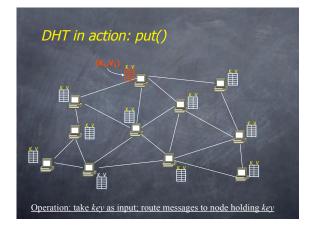

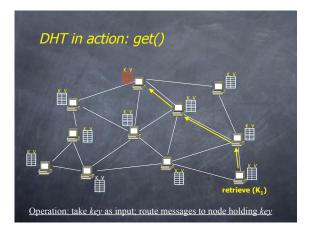

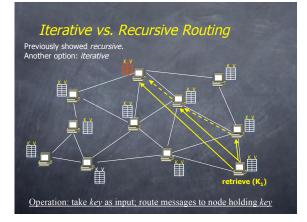

## DHT Design Goals

- An "overlay" network with:
   Flexible mapping of keys to physical nodes
   Small network diameter
   Small degree (fanout)
   Local routing decisions
   Robustness to churn
   Routing flexibility
   Decent locality (low "ctretch")

  - Decent locality (low "stretch")
- - No guarantees on persistence - Maintenance via soft state

## Peers vs Infrastructure

- Application users provide nodes for DHT
- Examples: filesharing, etc

- Set of managed nodes provide DHT service
- Perhaps serve many applications
- A p2p "incubator"?
  - We'll discuss this at the end of the tutorial

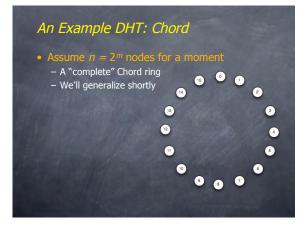

## Library or Service

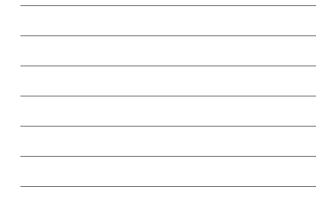

- - Runs on each node running application
  - Each application requires own routing infrastructure
- - Requires common infrastructure
  - But eliminates duplicate routing systems

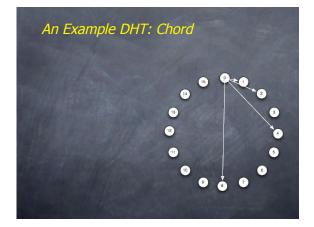

### DHT Outline

- High-level overview
   Fundamentals of structured network topologies
   And examples
   One concrete DHT

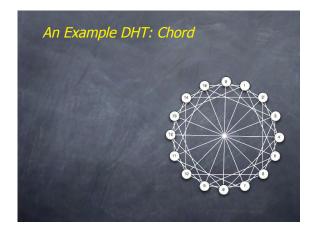

- Some systems issues
   Storage models & soft state
   Locality
   Churn management

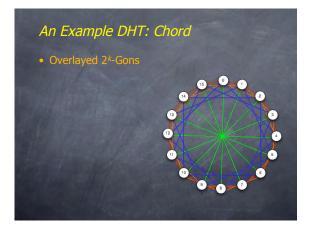

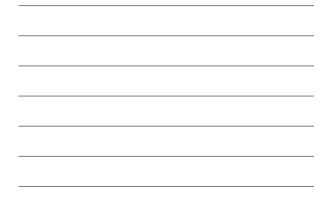

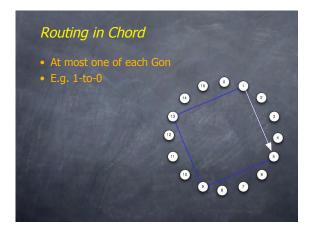

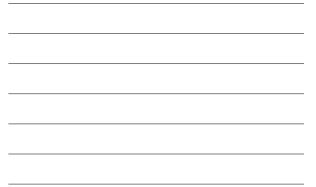

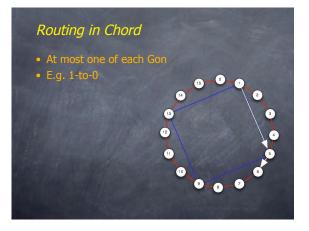

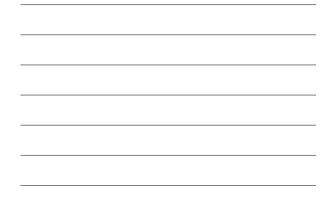

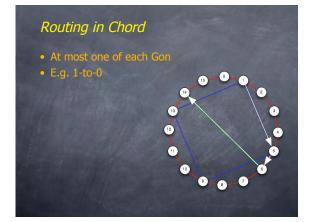

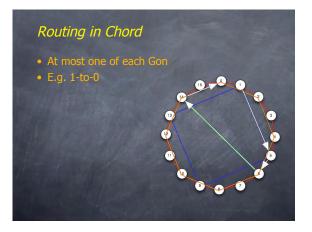

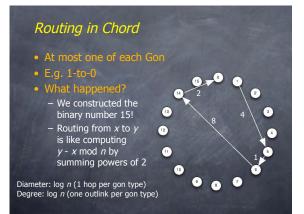

## What is happening here? Algebra!

- nderlying group-theoretic structure

   Recall a group is a set S and an operator such that:

   S is closed under •

   Associativity: (AB)C = A(BC) 

   There is an identity element  $I \in S \ s.t. \ IX = XI = X$  for all  $X \in S$  

   There is an inverse  $X^1 \in S$  for each element  $X \in S$ 
   $XX^1 = X^1X = I$ 
  • Ur
- - Elements {g<sub>1</sub>, ..., g<sub>n</sub>} s.t. application of the operator on the generators produces all the members of the group.
- Canonical example:  $(Z_{n'} +)$  Identity is 0
- A set of generators: {1}
  A different set of generators: {2, 3}

## Cayley Graphs

- - Vertices corresponding to the underlying set S
- Edges corresponding to the actions of the generators 6 ) 🎯

.

0

0

- $-S = Z \mod n \ (n = 2^k).$
- Generators {1, 2, 4, ..., 2<sup>k-1</sup>}
  That's what the gons are all about!
- ete) DHTs are Cayley graphs • Fact
- And they didn't even know it!
  - Follows from parallel InterConnect Networks (ICNs) • Shown to be group-theoretic [Akers/Krishnamurthy '89]

Note: the ones that aren't Cayley Graphs are *coset graphs*, a related group-theoretic structure

# So...? • Two questions: – How did this happen? - Why should you care?

## How Hairy met Cayley

- Uniformity of routing logic
   Efficiency/load-balance of routing and maintenance
   Generality at different scales

- I.e. isomorphic under swaps of nodes
   So routing from y to x looks just like routing from (y-x) to 0
   The routing code at each node is the same! Simple software.
   Moreover, under a random workload the routing responsibilities (congestion) at each node are the same!

C

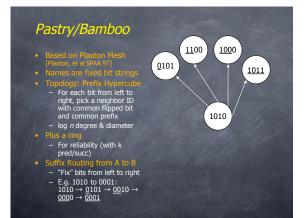

0 20 20 20 20 50

- Efficient routing with few neighbors to maintain
- - Made of smaller Cayley graphs connected by a new generator
     E.g. a Chord graph on 2<sup>m+1</sup> nodes looks like 2 interleaved (half-notch rotated) Chord graphs of 2<sup>m</sup> nodes with half-notch edges
     Again, code is nice and simple

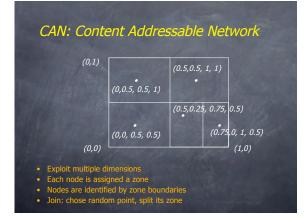

### Upshot

- Good DHT topologies will be Cayley/Coset graphs
   A replay of ICN Design

  - But DHTs can use funky "wiring" that was infeasible in ICNs
    All the group-theoretic analysis becomes suggestive
- Clean analyze efficiency – E.g. degree/diameter tradeoffs
- E.g. shapes of trees we'll see later for aggregation or join
- Really no excuse to be "sloppy"
   ISAM vs. B-trees

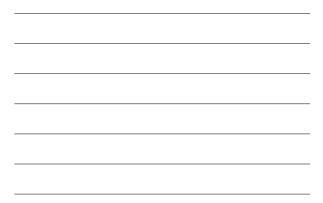

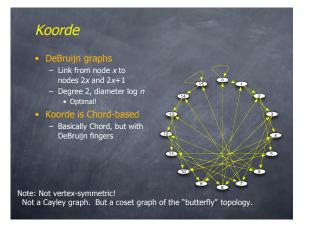

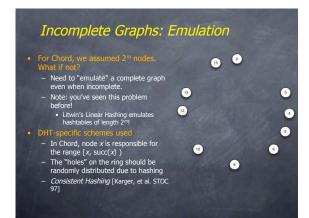

## Topologies of Other Oft-cited DHTs

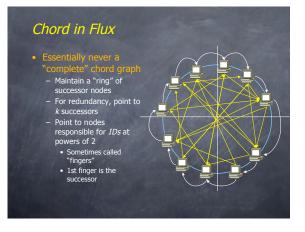

- Tapestry
   Very similar to Pastry/Bamboo topology

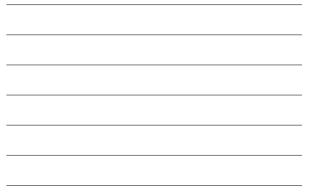

- Kademlia

   Also similar to Pastry/Bamboo
   But the "ring" is ordered by the XOR metric
   Used by the Overnet/eDonkey filesharing system
- Viceroy An emulated Butterfly network
- Symphony
  - A randomized "small-world" network

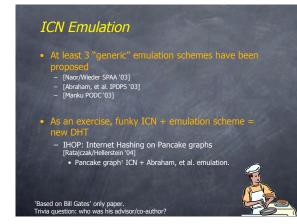

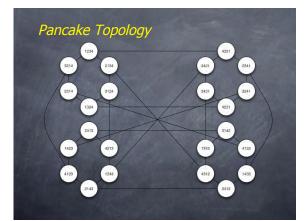

### A "Generalized DHT"

- Pick your favorite InterConnection Network
   Hypercube, Butterfly, DeBruijn, Chord, Pancake, etc.
- Pick an "emulation" scheme To handle the "incomplete" case
- Pick a way to let new nodes choose IDs - And maintain load balance

PhD Thesis, Gurmeet Singh Manku, 2004

### Storage Models for DHTs

- Up to now we focused on routing - DHTs as "content-addressable network"
- Implicit in the name "DHT" is some kind of storage
  - storage Or perhaps a better word is "memory" – Enables indirection in time
  - But also can be viewed as a place to store things
- Soft state is the name of the game in Internet systems

### A Note on Soft State

- Persistence via *storage* & *retry*
- Item published with a Time-To-Live (TTL) Storage node attempts to a Storage node attempts to preserve it for that time
   Best effort
   Publisher wants it to last longer?
   Must republish it (or renew it)
- Longer TTL = longer potential outage but less republishing
- Publisher eventually republishes elsehere
- On failure of a pu
- Storage node eventually "garbage collects"

- Nodes <u>close</u> on ring, but <u>far away</u> in Internet
  Goal: put nodes in routing table that result in few hops <u>and</u> low latency

### Locality-Centric Neighbor Selection

- Much recent work [Gummadi, et al. SIGCOMM '03, Abraham, et al. SODA '04, Dabek, et al. NSDI 04, Rhea, et al.
  - We saw flexibility in neighbor selection in Pastry/Bamboo
  - Can also introduce some randomization into Chord, CAN, etc.

- Analogous to ad-hoc networks

  - Ping random nodes
     Swap neighbor sets with neighbors

     Combine with random pings to explore
  - Provably-good algorithm to find nearby neighbors based on sampling [Karger and Ruhl 02]

Geometry and its effects [Gummadi, et al. SIGCOMM '03]

- - Choice of neighbors in the neighbor tables (e.g. Pastry)
  - Choice of routes to send a packet (e.g. Chord) - Cast in terms of "geometry"
    - But really a group-theoretic type of analysis
- Having a ring is very helpful for resilience Especially with a decent-sized "leaf set"
  - (successors/predecessors)

• Say ~ log n

### Handling Churn

- Bamboo IRhea, et al. USENIX C
- Pastry that doesn't go bad (?)
- - Session time? Life time?
    - For system resilience, session time is what matters.
- Three main issues Determining timeouts

  - Significant component of lookup latency under churn
  - Recovering from a lost neighbor in "leaf set" • Periodic, not reactive!
    - Reactive causes feedback cycles
  - Esp. when a neighbor is stressed and timing in and out Neighbor selection again

### Timeouts

- Recall Iterative vs. Recursive Routing
   Iterative: Originator requests IP address of each hop
   Message transport is actually done via direct IP
   Recursive: Message transferred hop-by-hop

- - Virtual coords begins to fail at higher churn rates

### DHTs Gave Us Equality Lookups

# What else might we want? Ange Search Aggregation Group By

- Join
   Intelligent Query Dissemination

- Theme
   All can be built elegantly on DHTs!
   This is the approach we take in PIER
   But in some instances other schemes are also reasonable
   I will try to be sure to call this out
   The flooding/gossip strawman is always available

## Range Search

- Numerous proposals in recent years
   Chord w/o hashing, + load-balancing [Karger/Ruhl SPAA '04, Ganesan/Bawa VLDB '04]
   Mercury [Bharambe, et al. SIGCOMM '04]. Specialized "small-world" DHT.
   P-tree [Crainiceanu et al. WebDB '04]. A "wrapped" B-tree variant.

  - P-Grid [Aberer, CoopIS '01]. A distributed trie with random links.
- (Apologies if I missed your favorite!)
   We'll do a very simple, elegant scheme here
   Prefix Hash Tree (PHT). [Ratnasamy, et al '04]

  - Works over any DHT – Simple robustness to failure
  - Hints at generic idea: direct-addressed distributed data structures

## Prefix Hash Tree (PHT)

- Recall the trie (assume binary trie for now)
   Binary tree structure with edges labeled 0 and 1
   Path from root to leaf is a prefix bit-string
- A key is stored at the minimum-distinguishing prefix (depth)
   PHT is a bucket-based trie addressed via a DHT
- Modify trie to allow b items per leaf "bucket" before a split
   Store contents of leaf bucket at DHT address corresponding to prefix
  - So far, not unlike Litwin's "Trie Hashing" scheme, but hashed on a DHT.

• Punchline in a moment...

### PHT Search

### Reusable Lessons from PHTs

- Direct-addressing a lovely way to emulate robust, efficient "linked" data structures in the network
- Direct-addressing requires regularity in the data space partitioning

   *E.g.* works for regular space-partitioning indexes (tries, quad trees)
  - Not so simple for data-partitioning (B-trees, R-trees) or irregular space partitioning (kd-trees)

### Aggregation

- Two key observations for DHTs DHTs are multi-hop, so hierarchical aggregation can reduce BW

  - E.g., the TAG work for sensornets [Madden, OSDI 2002] DHTs provide tree construction in a very natural way

- Hold that thought!

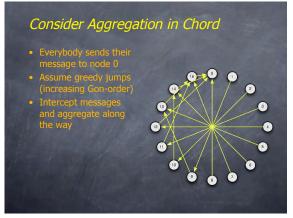

### An API for Aggregation in DHTs

- Uses a basic hook in DHT routing
   When routing a multi-hop msg, intermediate nodes can
   intercept

- Idea
   To aggregate in a DHT, pick an aggregating ID at random
   All nodes send their tuples toward that ID
   Nodes along the way intercept and aggregate before forwarding

- Questions
   What does the resulting agg tree look like?
   What shape of tree would be good?
- Note: tree-construction will be key to other tasks!

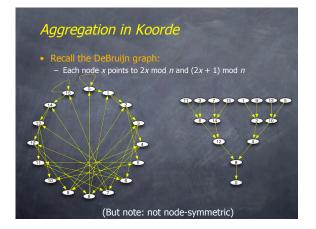

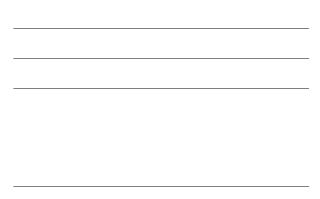

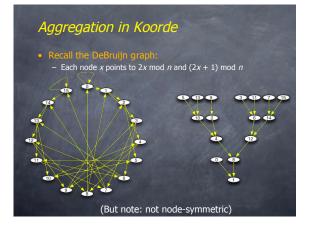

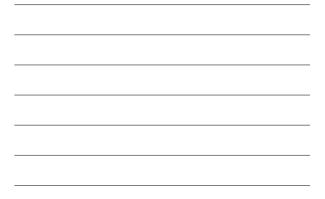

### Consider Aggregation in Chord

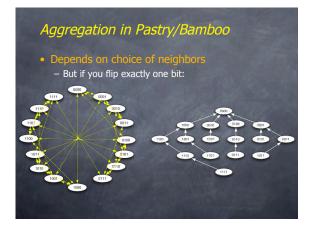

# Aggregation in Pastry/Bamboo • Depends on choice of neighbors • But if you flip exactly one bit each hop:

### Metrics for Aggregation Trees

- What makes a good/bad agg tree?
  Number of edges? No!

  Always n-1. With distributive/algebraic aggs, msg size is fixed.
  Degree of fan-in

  Affects congestion
  Height

  Determines latency

  Predictability of subtree shape

  Determines ability to control timing tightly

  Stability in the face of churn

  Changing tree shape while accumulating can result in errors
  Subtree size distribution
  Affects "jeopardy" of lost messages
  - Affects "jeopardy" of lost messages

### So what if I don't have a DHT?

- Need another tree-construction mechanism
   There are many in the NW literature (e.g. for multicast)
   Require maintenance messages akin to DHTs
   Do you maintain for the life of your query engine? Or setup/teardown as needed?
- Can pick a tree shape of your com

   Not at the mercy of the DHT topologies
   E.g. could do high fan-in trees to minimize latency
- As we noted before, we will reuse tree-construction for multiple purposes
  - It's handy that they're trivial in DHTs
  - But could reuse another scheme for multiple purposes as well

• Or, can do aggregation via gossip [Kempe, et al FOCS '03

### Group By

- A piece of cake in a DHT

   Every node sends tuples toward the hash ID of the grouping columns
  - An agg tree is naturally constructed per group
- Note nice dual-purpose use of DHT
   Hash-based partitioning for parallel group by
   Just like parallel DBMS (Gamma, the *Exchange* op in Volcano)
  - Agg tree construction in multi-hop overlay network

### Hash Join

- We just did hash-based group by.
  Hash-based join is roughly the same deal, twice:

  Given R.a Join S.b
  Each node:

  sends each R tuple toward H(R.a)
  sends each S tuple toward H(S.b)

  - Hash-based partitioning for parallel hash join
     Tree construction (no reduction along the way here, though)
- Note t
- A tree is constructed per hash destination!

  - That's a lot of trees!
    No big deal for the DHT -- it already had that topology there.

### Fetch Matches Join

- Essentially a distributed index join
   Name comes from R\* (Mackert & Lohman)
- Assume <S.b, tuple> was already "published" (indexed)
- - Each S.b value will get some subset of the nodes visiting it
  - So a lot of "partial" trees
     Note: if S.b is *not* already indexed in the DHT via S.b, that has to happen on the fly • Half a hash join :-)

### Symmetric Semi-Join and Bloom Join

- S

  - But do it to both Sides or are je.
    Rewrite R.a Join S.b as

    (<S.ID,S.b> semi-join <R.id,R.a>) join R.a join S.b
    Latter 2 joins can be Fetch Matches
- B
- Requires a bit more finesse here
   Aggregate R.a Bloom filters to a fixed hash ID. Same for S.b.
  - All the R.a Bloom filters are OR'ed, eventually multicasted to all nodes storing S tuples
     Symmetric for S.b Bloom filter

  - Can in principle stream refining Bloom filters

### Query Dissemination

- Up to now we conveniently ignored this!

- Case 1: Broadcast

   As far as we know, all nodes need to participate
   As far as we know, all nodes need to participate

   - Need to have a broadcast tree out of the query node
  - This is the opposite of an aggregation tree!But how to instantiate it?
- - Each nodes sends query to all its neighbors - Problem: nodes will receive query multiple times
    - wasted bandwidth

### SCRIBE

- Redundancy-free broadcast
  Upon joining the network, route a message to some canonical hash ID
  - Parent intercepts msg, makes a note of new child, discards message
  - At the end, each node knows its children, so you have a broadcast tree Tree needs to deal with joins and leaves on its own; the DHT won't help.
  - MSR/Rice, NGC '01

## Query Dissemination II Suppose you have a simple equality query – Select \* From R Where R.c = 5 A rec is already indexed in the Diff, can role que DHT Query Dissemination is an "access method" Basically the same as an index Can take more complex quer parts - Select \* From R, S, T Where R.a = S.b And S.c = T.d And R.c = 5

### DHTs in PIER

- Query Broadcast (TC)
- Indexing (CBR + S)
- Range Indexing Substrate (CBR+S)
   Hash-partitioned parallelism (CBR)
- Hash tables for group-by, join (CBR + S)
- Hierarchical Aggregation (TC + S)

TC = Tree Construction CBR = Content-Base Routing S = Storage

Hash Index B+-Tree Exchange

### Native Simulation

- Entire system is event-driven
  Enables discrete-event simulation to be "slid ir
- - Replaces lowest-level networking & scheduler
     Runs all the rest of PIER
- Very helpful for debugging a massively distributed system!

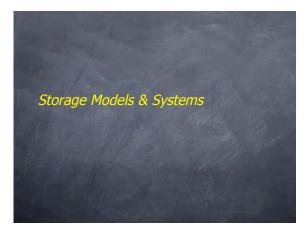

43

### Initial Tidbits from PIER Efforts

- "Multiresolution" simulation critical
   Native simulator was hugely helpful
   Emulab allows control over link-level performance
   PlanetLab is a nice approximation of reality
- Need to have a traced execution mode.
   Radiological dye? Intensive logging?
- Do workdoaps on rww recentorogy, mishifactures
   E.g. Bamboo aggressively changes neighbors for single-message resilience/performance
   Can wreak havoc with stateful aggregation trees
   E.g. returning results: SELECT \* from Firewalls
   1 MegaNode of machines want to send you a tuple!
   A relational query processor w/o storage
   Where's the metadata?

### Traditional FileSystems on p2p?

- Lots of projects

   OceanStore, FarSite, CFS, Ivy, PAST, etc.
- Lots or challenges
   Motivation & Viability
   Short & long term
   Resource mgmt
   Load balancing w/heterogeneity, etc.
   Economics come strongly into play
   Billing and capacity planning?
   Reliability & Availability
   Replication, server selection
   Wide-area replication (+ consistency of updates)
   Security Security
   Encryption & key mgmt, rather than access control

### Non-traditional Storage Models

- LOCKSS
- Palimpsest, OpenDHT

### LOCKSS

### [Maniatis, et al. SOSP '04]

- Academic publishing is moving from paper to digital *leasing*
- Librarians are scared with good reason Access depends on the fate of the publisher
  - Time is unkind to bits after decades

  - Plenty of enemies (ideologies, governments, corporations)
- Goal: Preserve access for local patrons, for a very long time

### Protocol Threats

- Assume conventional platform/social attacks
  Mitigate further damage through protocol
  Top adversary goal: Stealth Modification

- Modify replicas to contain adversary's version
- Hard to reinstate original content after large proportion of replicas are modified
- - Denial of service
  - System slowdown
  - Content theft

### The LOCKSS Solution

- Peer-to-peer auditing and repair system for replicated documents / no file sharing
  A peer periodically audits its own replica, by calling an opinion poll
  When a peer suspects an attack, it raises an alarm for a human operator

  Correlated failures
- - Correlated failures
  - IP address spoofing
  - System slowdown
- 2nd iteration of a deployed system

### Sampled Opinion Poll

- Each peer holds reference list of peers it has discovered friends list of peers it knows externally friends have rate of bit ro
- Take a sample of the reference list
   Invite them to send a hash of their replica
- - Sleep blissfully
     Repair
- Overwhelming agreement (>70%)
   Overwhelming disagreement (<30%)</li>
   Repair
   Too close to call *\** Raise an alarm
   To repair, the peer gets the copy of somebody who disagreed and then reevaluates the same votes

### Reference List Update

- Take out voters in the poll
- So that the next poll is based on different group
- Replenish with some "strangers" and some "friends"
  - Strangers: Accepted nominees proposed by voters
  - Friends: From the friends list
  - The measure of favoring friends is called churn factor

### LOCKSS Defenses

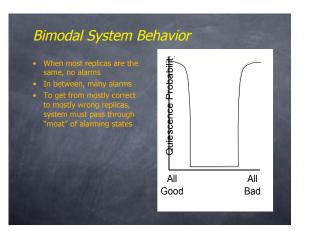

- Limit the rate of operationBimodal system behaviorChurn friends into reference list.

### Limit the rate of operation

- Peers determine their rate of operation autonomously

   Adversary must wait for the next poll to attack through the protocol
- No operational path is faster than others

   Artificially inflate "cost" of cheap operations
   No attack can occur faster than normal ops

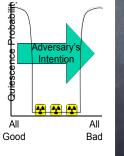

- When most replicas are the same, no alarms In between, many alarms To get from mostly correct to mostly wrong replicas, system must pass through "moat" of alarming states

### Bimodal System Behavior

- When most replicas are the same, no alarms In between, many alarms To get from mostly correct o mostly wrong replicas, system must pass through 'moat" of alarming states

### Churn Friends into Reference List

- Churn adjusts the bias in the reference list
  High churn favors friends

  Reduces the effects of Sybil attacks
  But offers easy targets for focused attack

- - LOW Chain Hardon's Strangers
     It offers Sybil attacks free reign
     Bad peers nominate bad; good peers nominate some bad
     Makes focused attack harder, since adversary can predict
     less of the poll sample

### Palimpsest [Roscoe & Hand, HotOS 03]

- Small and very simple
  Soft-capacity for service providers
  Congestion-based pricing

- Automatic space reclamationFlexible client and server policies
- We'll ignore the economics

### Service Model for Ephemeral Storage

- Data highly available for limited period of time
- Secure from unauthorized readers
- Resistant to DoS attacks
- Tradeoff cost/reliability/performance

- Charging that makes economic sense
- Capacity planning
- Simplicity of operation and billing

### How does it do this?

- Erasure code it
- Route it through a network of simple block stores Pay to store it
- Each block store is a fixed-length FIFO Block stores may be owned by multiple providers
  - Block stores don't care who the users are
  - No one store needs to be trusted
  - Blocks are eventually lost off the end of the queue

### Storing a file

- - Use a rateless code to spread blocks into fragments
     Rabin's IDA over GF(2<sup>16</sup>), 1024-byte blocks
- - Security, authenticity, identification

    AES in Offset Codebook Mode

- Fragment Placement Encrypt: (SHA256(name) ⊕ frag.id) ⇒ 256-bit ID Send (fragment, ID) to a block store using DHT
   Any DHT will do

### What happens at the block store?

- Use > 1 per node for scaling
- Note: fragment ID is *not* related to content (c.f. CFS)
- No authentication needed

Frag. 0xe044 Frag. 0x7bb1

New fragment

0x04f1

Hash Table

Frag. 0xe042

Frag. 0x04f1 Frag. 0x6673 Frag. 0xffe4

Frag. 0x1167

Frag. 0x0040

٧

### Retrieving a file

- Generate enough fragment IDs
  Request fragments from block stores
  Wait until *n* come back to you
  Decrypt and verify
  Invert the IDA *Voila!*

Unfortunately...

### Files disappear

- This is a storage system which, in use, is guaranteed to forget everything

   c.f. Elephant, Postgres, etc.
- Not a problem for us provided we know how long files stay around for
  - Can refresh files
  - Can abandon them
  - Note: there is no delete operation
- How do we do this?

### Sampling the time constant

- How long fragment takes to reach end of queue Clients query block stores for  $\tau$
- Operation piggy-backed on reads/writes
- Maintain exponentially-weighted estimate of system  $\tau, \ \tau_{\rm s}$
- Fragment lifetimes Normally distributed around  $\tau_s$
- Use this to predict file lifetimes
   Allows extensive application-specific tradeoffs

### Trustworthy P2P

- Many challenges here. Examples:
   Authenticating peers
   Authenticating/validating data
   Stored (poisoning) and in flight
   Ensuring communication
   Validating distributed computations
   Avoiding Denial of Service
   Ensuring fair resource/work allocation
   Ensuring privacy of messages
   Content, quantity, source, destination
   Abusing the power of the network
   We'll just do a sampler today

### Free Riders

- - Lots of people download
  - Few people serve files
- - If there's no incentive to serve, why do people do so?
  - What if there are strong disincentives to being a major server?

### Simple Solution: Threshholds

- Many programs allow a threshold to be set
   Don't upload a file to a peer unless it shares > k
- files
- What's k?
- How to ensure the shared files are interesting?

### BitTorrent

- suprnova.org, chat rooms, etc. serve ".torrent" files
  metadata including "tracker" machine for a file
- Barte
  - Download one (random) chunk from a storage peer, slowly
     Subsequent chunks *bartered* with concurrent downloaders
  - As tracked by the tracker for the file
  - The more chunks you can upload, the more you can download
  - Download speed starts slow, then goes fast
  - Great for large files Mostly videos, warez

### One Slide on Game Theory

- Typical game theory setup

   Assume self-interested (selfish) parties, acting autonomously

   Define some benefit & cost functions

   Parties make "moves" in the game

   With resulting costs and benefits for themselves and others

   A Nash equilibrium:

   A state where no party increases its benefit by moving

   Note:

   Equilibria need not be unique nor equal
  - Equilibria need not be unique nor equal
    Time to equilibrium is an interesting computational twist

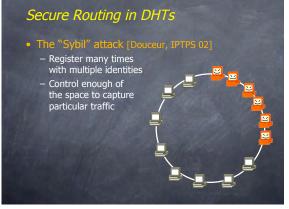

- Mechanism Design

   Design the states/moves/costs/benefits of a game
   To achieve particular globally-acceptable equilibria
   I.e. selfish play leads to global good

### DAMD P2P!

- Distributed Algorithmic Mechanism Design (DAMD)
   A natural approach for P2P
- - Every node *n* maintains a *usage record*:

  - Every node *n* maintains a *usage record:*Advertised capacity
    Hosted list of objects n is hosting (nodeID, objID)
    Published list of objects people host for *n* (nodeID, objID)
    Can publish if capacity *p* ∑(published list) > 0
    Recipient of publish request should check *n's* usage record
    Need schemes to authenticate/validate usage records
    Selfish Audits: *n* periodically checks that the elements of its hosted list *p* periodically picks a peer and checks all its hosted list items

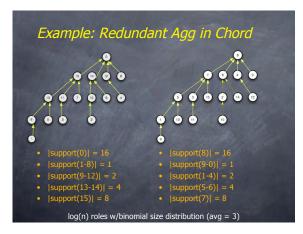

### Squelching Sybil

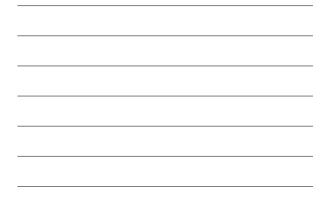

- Weak secure IDs ID = SHA-1(IP address)
- Assume attacker controls a modest number of nodes Before routing through a node, challenge it to produce the right IP address
  - Requires iterative routing

### Redundant Computation

- Correctness via redundancy An old idea (e.g. process pairs)

  - Applied in an adversarial environment
  - Using topological properties of DHTs
- Two Themes
   Change "support" contents per peer across copies
   Equalize "influence" of each peer

### OpenDHT

- hared DHT service The Bamboo DHT Hosted on PlanetLab Simple RPC API You don't need to deploy or host to play with a real DHT! Bayrooud for bits
- Needn't be as big as PIER! Example: FreeDB replaceme
- ReDiR (karp, et al. 1979; '04) Recitive Distributed Rendezvous Enables multiple apps on subsets of nodes New resource mgmt scheme to do fair-share storage

### OpenHash -> Open DHT

Open DHT is the new name for the OpenHash project. Same project, same goals, same people!

### Project Overview

Open DHT is a *publicly accessible DHT service*; it allows any client code, running on any host on on (key, value) pairs. No credentials or accounts are required to use the service, which clients invo RPC). pen DHT runs on a collection of widely distributed infrastructure hosts (currently on PlanetLab).

### What Does Open DHT Provide?

Open DHT makes it easy for developers everywhere to build and test new, broadly useful distribu-them. The high-availability (key, value) store provided by Open DHT takes much of the client-sid rendezvons, and other communication models frequently employed by distributed applications. Why a DHT Service?

### Much Fun to Be Had Here

- Potentially high-impact area
   New classes of applications enabled
   A useful question: "What apps need/deserve this scale" Intensity of the scale keeps the research scope focused – Zero-administration, sub-peak performance, semantic homogeneity, etc.
  - A chance to reshape the Internet
    - More than just a packet delivery service
    - arphi is an effort in this direction

### Much Fun to Be Had Here

- Rich cross-disciplinary rallying point
  - Networks, algorithms, distributed systems,
  - databases, economics, security...
  - Top-notch people at the table – Many publication venues to choose from
    - Including new ones like NSDI, IPTPS, WORLDS

### Much Fun to Be Had Here

- DHT and similar overlays are a real breakthough
   Building block for data independence
- Multiple metaphors
   Hashtable storage/index
   Content-addressable routing
   Topologically interesting tree construction
   Each stimulates ideas for distributed computation
- Rela Relatively solid DHT implementations - Bamboo, OpenDHT (Intel & UC Berkeley) - Chord (MIT)

### The DB Community Has Much to Offer

- Complex (multi-operator) queries & optimization
   NW folks have tended to build single-operator "systems"
   E.g. aggregation only, or multi-d range-search only
   Adaptivity required
   But may not look like adaptive QP in databases...
- Deal with streaming, clock jitter and soft state!
- Data reduction techniques
   For visualization, approximate query processing
   For visualization, approximate query processing
- Quite different from the ones the NW and systems folks envision
- Recursive query processing
   The network *is* a graph!
