Privilege Escalation in Windows OS

by Zohaib & Vlad

What is Privilege Escalation?

An act of exploiting a bug, design flaw or configuration oversight with the goal to gain elevated access to application resources

- Gives the ability to perform unauthorized actions in software, web apps, operating systems

What is Privilege Escalation?

Vertical

Accesses to functions that are reserved for higher privilege users or applications.

- gaining administrative privileges
- Jailbreaking Devices
- Lock Screen Bypass

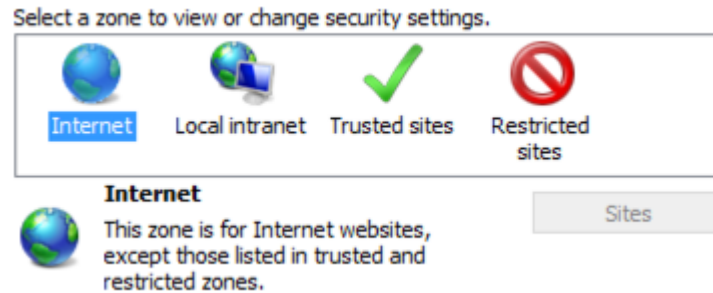

Horizontal

Accesses functions that are accessible by other normal users.

- Accessing accounts on the same user level
- Stealing usernames/passwords

Vertical: Cross-zone scripting

A web browser exploit that takes advantage of a **zone-based vulnerability**

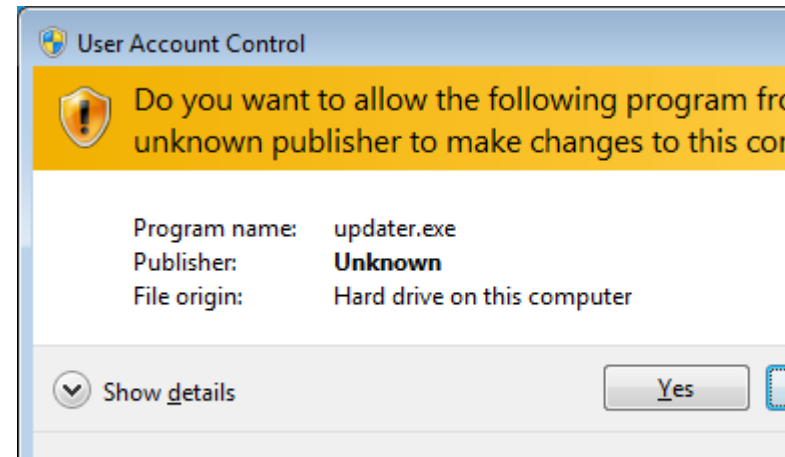

<http://windowsupdate.microsoft.com%2f.example.com/>

Windows Permission Structure

- root is “Local System” Account
- Windows UAC (User Account Control)
 - disabled admin account, instead uses UAC
- “sudo” is “runas” to run with privileges

Types of Accounts:

- Local User
- Domain User
- The LocalSystem

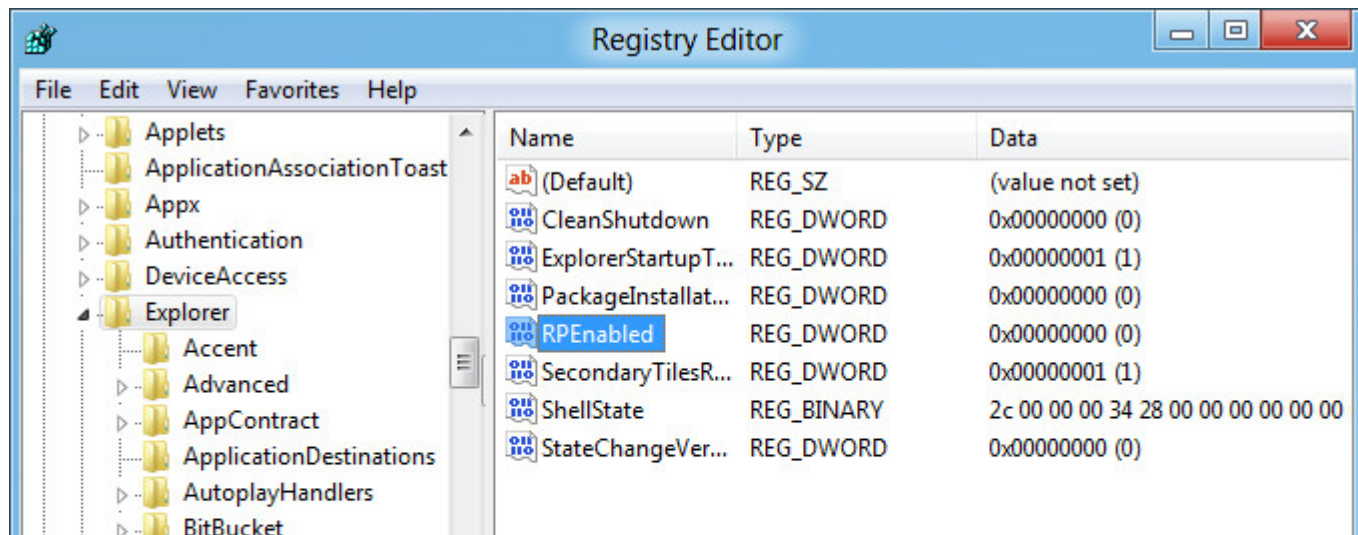

Windows with User Access Control

- All users run as an unprivileged user by default, even when logged on as an Administrator.
- Once running, the privilege of an application cannot be changed.
- Users are prompted to provide explicit consent before using elevated privilege, which then lasts for the life of the process.

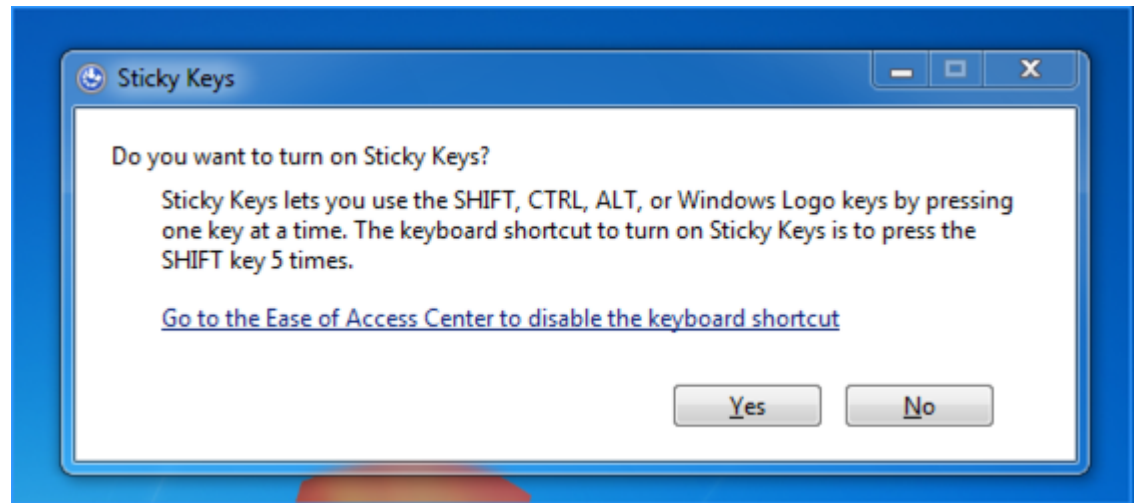

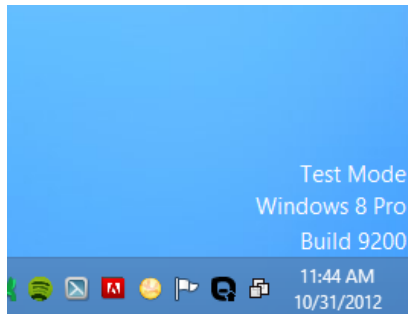

Windows OS Privilege Escalation

- replacing “screensaver” binary
- scan the registry for
 - logon Information
 - network credentials
 - private keys
 - Many different tools that will do this task for you

Windows OS Privilege Escalation

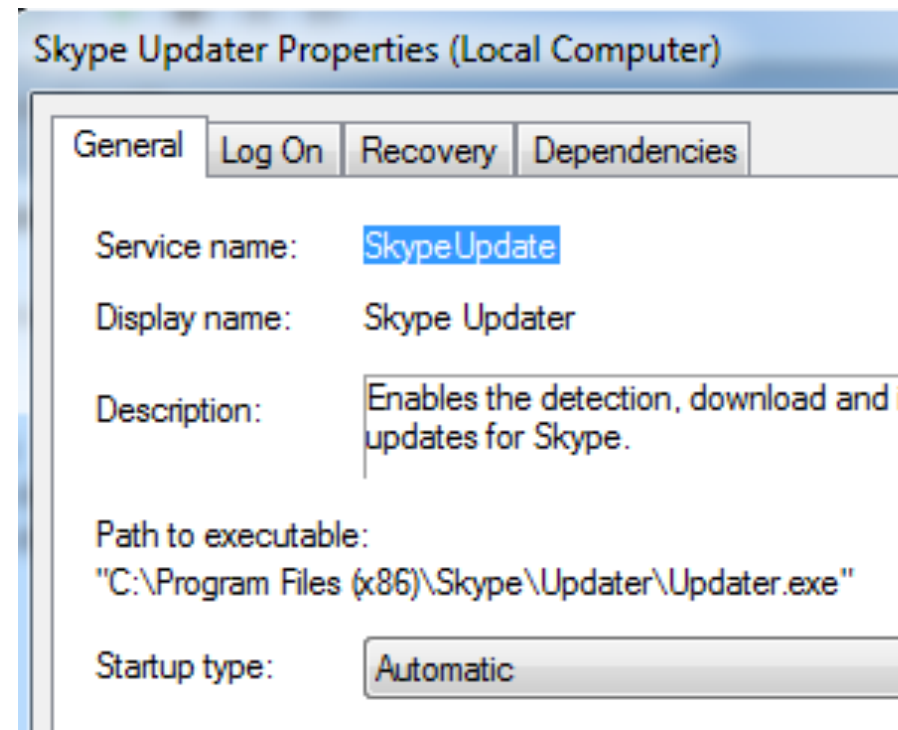

- exploit design flaws
 - find processes that run as SYSTEM using GUI or tools

- retrieve user hashes
 - Retrieve a user hash from Local Security Authority Subsystem Service (LSASS)
 - Corrupt the memory and use the hash

Windows OS Privilege Escalation

- missing autorun programs
- service quoting

Windows OS Privilege Escalation

- Internet Explorer Elevation Policy

Integrity Access Level (IL)	System Privileges
High	Administrative (Process can create and delete objects with full control)
Medium	User (Process can create and delete objects with full control)
Low	Untrusted (Process can create and delete objects with full control)

Value	Result
3	Protected Mode silently launches the broker as a medium integrity process.
2	Protected Mode prompts the user for permission to launch the process as a medium integrity process.
1	Protected Mode silently launches the broker as a low integrity process.
0	Protected Mode prevents the process from launching.

Compromise IE

Start a server on localhost

Windows OS Privilege Escalation

- services run under Local System or with Elevated flags through stolen access tokens

Recent Vulnerability Demo

Security Tokens in Windows

- **Access Token**
- **Impersonation Token**
- **Impersonation**

Impersonation level
SecurityAnonymous
SecurityIdentification
SecurityImpersonation *
SecurityDelegation

Exploit Details

- Allows to run services and programs with Elevated privileges
- Severity Rating: **“Important”**
- Proof of Concept: Disables UAC popup
- The token may allow you to:
 - inject DLLs into system processes
 - start up ASPNET / IIS server processes
 - get access to LOCAL SYSTEM

Writing an exploit

- Find an auto-elevated executable
 - Such as “ComputerDefaults.exe”
 - These executables set up a cache point in the registry (regsvr32.exe)
- Look up Application Compat DB: `sysmain.sdb`
- Capture the “Impersonation Token”
 - by using the vulnerability in the cache system
- Start a new process using “runas”
- Assign its impersonation token using “SetThreadToken” and it set a “SecurityImpersonation” level

Google's Project Zero

- Aims to improve the security of any software
- Locating and reporting large number of vulnerabilities
- Issues are filed in an external database which is initially reported to vendor
- 90-day policy

Disclosing the vulnerability early

Disclosing the vulnerability early

- Who do you think is right in this issue Google or Microsoft?
- Do you think 90-days is fair for vulnerability disclosure?
- How much time should a vulnerability patch take? (90-days, 180-days?)
