Last updated: June 7, 2017
“Using expert advice”
A basic binary setting

On each one of $T$ days:

We need to make a binary decision (Up/Down).

$n$ “experts” give us their prediction (Up/Down).

Based on their advice, we make a choice.

We then find out whether our choice is correct.

If our choice is wrong, we pay a penalty of 1.

If our choice is right, we do not pay anything.

Our goal, of course, is to pay as little as possible.

"Using expert advice"
“Using expert advice”
A basic binary setting

How well can we do?

If all “experts” are bad, we cannot do too well.

We would like to do 
*almost as well as the best expert*, with *hindsight*.
The Weighted Majority algorithm
[Littlestone-Warmuth (1994)]

Choose a parameter $0 < \eta \leq \frac{1}{2}$.

Assign each expert a weight.

The weight of the $i$-th expert at day $t$ is $w_i^{(t)}$.

On day 1, all weights are 1: $w_i^{(1)} = 1$, $i = 1, 2, \ldots, n$.

At day $t$, predict Up or Down according to the weighted majority of the experts.

Predict up, if $\sum_{i \in U(t)} w_i^{(t)} \geq \sum_{i \in D(t)} w_i^{(t)}$,

$U(t), D(t)$ – sets of experts predicting Up/Down at day $t$.

Update the weights:

$$w_i^{(t+1)} = \begin{cases} 
  w_i^{(t)} & \text{if } i \text{ was correct on day } t \\
  (1 - \eta)w_i^{(t)} & \text{otherwise}
\end{cases}$$
The Weighted Majority algorithm

[Littlestone-Warmuth (1994)]

\[ \text{cost}^{(T)}(WM_\eta) \] – Number of mistakes of \( WM_\eta \) up to time \( T \).

\[ \text{cost}^{(T)}(EXP_i) \] – Number of mistakes of \( EXP_i \) up to time \( T \).

**Theorem:** For every \( i = 1,2, \ldots, n \),

\[ \text{cost}^{(T)}(WM_\eta) \leq 2(1 + \eta)\text{cost}^{(T)}(EXP_i) + \frac{2 \ln n}{\eta} \]

In particular, the inequality holds for the best expert.

Thus, the cost of the Weighted Majority algorithm is only slightly larger than twice the cost of the best expert!

(We can do even better using a randomized algorithm.)
The Weighted Majority algorithm
[Littlestone-Warmuth (1994)]

**Theorem:** For every $i = 1, 2, ..., n$,

$$cost^{(T)}(WM_\eta) \leq 2(1 + \eta)cost^{(T)}(EXP_i) + \frac{2 \ln n}{\eta}$$

**Proof:**

Let $W^{(t)} = \sum_{i=1}^{n} w_i^{(t)}$. Clearly, $W^{(1)} = n$.

If $WM_\eta$ makes a mistake in day $t$, then

$$W^{(t+1)} \leq \left(\frac{1}{2} + \frac{1}{2} (1 - \eta)\right) W^{(t)} = \left(1 - \frac{\eta}{2}\right) W^{(t)}.$$

$$W^{(T+1)} \leq n \left(1 - \frac{\eta}{2}\right)^{cost^{(T)}(WM_\eta)}$$

$$W^{(T+1)} \geq w_i^{(T+1)} = (1 - \eta)^{cost^{(T)}(EXP_i)}$$
The Weighted Majority algorithm

[Littlestone-Warmuth (1994)]

\[(1 - \eta)^{\text{cost}^{(T)}(\text{EXP}_i)} \leq W^{(T+1)} \leq n \left(1 - \frac{\eta}{2}\right)^{\text{cost}^{(T)}(W M_\eta)}\]

\[\text{cost}^{(T)}(\text{EXP}_i) \ln(1 - \eta) \leq \text{cost}^{(T)}(W M_\eta) \ln \left(1 - \frac{\eta}{2}\right) + \ln n\]

\[\text{cost}^{(T)}(W M_\eta) \leq \frac{\ln(1 - \eta)}{\ln \left(1 - \frac{\eta}{2}\right)} \text{cost}^{(T)}(\text{EXP}_i) + \frac{\ln n}{-\ln \left(1 - \frac{\eta}{2}\right)}\]

\[\leq \frac{\eta + \eta^2}{\frac{\eta}{2}} = 2(1 + \eta) \leq \frac{\ln n}{\frac{\eta}{2}} = \frac{2 \ln n}{\eta}\]

Using \(x \leq -\ln(1 - x) \leq x + x^2\), for \(x \leq \frac{1}{2}\).
\[ x \leq -\ln(1 - x) \leq x + x^2, \quad \text{for } x \leq \frac{1}{2}. \]
“Using expert advice”

A more general setting

On each one of $T$ days:

(Each one of $n$ “experts” suggests a *course of action.*)

We choose a *(probability) distribution* over the *experts*.

The *costs* of choosing each *expert* are revealed.

All costs are in $[-1,1]$.

We pay the *average* cost according to the *distribution* chosen.

Our goal is to minimize our total cost.

Alternative interpretation: On each day a *random* expert is drawn according to the *distribution* chosen. We pay the *expected* cost.

The Multiplicative Weights algorithm
[Cesa-Bianchi, Mansour, Stoltz (2007)]

Choose a parameter $0 < \eta \leq \frac{1}{2}$.

The weight of expert $i$ at day $t$ is $w_i^{(t)}$.

$$w_i^{(1)} = 1, \ i = 1,2, \ldots, n.$$

At day $t$ use the distribution:

$$p^{(t)} = \left( \frac{w_1^{(t)}, w_2^{(t)}, \ldots, w_n^{(t)}}{W(t)} \right) \quad W(t) = \sum_{i=1}^{n} w_i^{(t)}$$

Let $m^{(t)} = \left( m_1^{(t)}, m_2^{(t)}, \ldots, m_n^{(t)} \right)$ be the costs at day $t$.

Update the weights:

$$w_i^{(t+1)} = w_i^{(t)} \left( 1 - \eta m_i^{(t)} \right)$$
The Multiplicative Weights algorithm  
[Cesa-Bianchi, Mansour, Stoltz (2007)]

**Theorem:** Assume that $m_i^{(t)} \in [-1,1]$ and that $0 < \eta \leq \frac{1}{2}$.

Let $p^{(t)}$ be the distribution used by $MW_\eta$ at day $t$.

Then, for every $i = 1,2, \ldots, n$,

$$
\sum_{t=1}^{T} p^{(t)} \cdot m^{(t)} \leq \sum_{t=1}^{T} m_i^{(t)} + \eta \sum_{t=1}^{T} (m_i^{(t)})^2 + \frac{\ln n}{\eta}
$$

$$
cost^{(T)}(MW_\eta) \leq \eta \sum_{t=1}^{T} |m_i^{(t)}|
$$

$$
cost^{(T)}(EXP_i) \leq \eta \sum_{t=1}^{T} |m_i^{(t)}|
$$
The Multiplicative Weights algorithm
[Cesa-Bianchi, Mansour, Stoltz (2007)]

\[
\ln \frac{W^{(T+1)}}{W^{(1)}} = \sum_{t=1}^{T} \ln \frac{W^{(t+1)}}{W^{(t)}} = \sum_{t=1}^{T} \ln \sum_{i=1}^{n} p^{(t)} (1 - \eta m^{(t)}_i)
\]

\[
= \sum_{t=1}^{T} \ln (1 - \eta p^{(t)} \cdot m^{(t)}) \leq -\eta \sum_{t=1}^{T} p^{(t)} \cdot m^{(t)}
\]

\[
\ln \frac{W^{(T+1)}}{W^{(1)}} \geq \ln \frac{w^{(T+1)}_i}{n} = -\ln n + \sum_{t=1}^{T} \ln (1 - \eta m^{(t)}_i)
\]

\[
\geq -\ln n - \eta \sum_{t=1}^{T} m^{(t)}_i - \eta^2 \sum_{t=1}^{T} (m^{(t)}_i)^2
\]

Using \(-x - x^2 \leq \ln(1 - x) \leq -x\), for \(x \leq \frac{1}{2}\).
Applications of the Multiplicative Weights algorithm

Learning a linear classifier (The Winnow algorithm)

Boosting the performance of weak learners (cf. Adaboost)

Approximately solving 0-sum 2-player games

Approximately solving packing Linear Programs

Approximately solving covering Linear Programs

Special case: Multicommodity flow

Approximately solving Semidefinite Programs

Special case: SDP relaxation of MAX CUT

\ldots
Assume, w.l.o.g., that the hyperplane passes through the origin and that $\mathbf{x} \in (\mathbb{R}^+)^n$, $\mathbf{1} \cdot \mathbf{x} = 1$. 
Learning a Linear Classifier

Let $\mathbf{a}_1, \mathbf{a}_2, \ldots, \mathbf{a}_m \in \mathbb{R}^n$,

Assume there exists $\mathbf{x} \in (\mathbb{R}^+)^n$, $\mathbf{1} \cdot \mathbf{x} = 1$, such that $\mathbf{a}_j \cdot \mathbf{x} \geq \varepsilon$, for $j \in [m]$.

Find $\mathbf{x}' \in (\mathbb{R}^+)^n$, $\mathbf{1} \cdot \mathbf{x}' = 1$, such that $\mathbf{a}_j \cdot \mathbf{x}' \geq 0$, for $j \in [m]$.

Let $\rho = \max_j \|a_j\|_{\infty}$. 
Learning a Linear Classifier - The Winnow algorithm [Littlestone (1987)]

Experts correspond coordinates (also known as features).

Run $MW_\eta$ with $\eta = \frac{\varepsilon}{2\rho}$.

In each iteration, if $p^{(t)}$ is a good classifier, stop.

Otherwise, let $j$ be such that $p^{(t)} \cdot a_j < 0$.

Let $m^{(t)} = -\frac{a_j}{\rho}$.

**Theorem:** If there exists a classifier $x^*$ such that $a_j \cdot x^* \geq \varepsilon$, $j \in [m]$, then Winnow finds a classifier $x$ such that $a_j \cdot x \geq 0$, $j \in [m]$, after at most $T = \frac{4\rho^2}{\varepsilon^2} \ln n$ iterations.
Learning a Linear Classifier - The Winnow algorithm [Littlestone (1987)]

For every coordinate (expert) $i$ we have:

$$
\sum_{t=1}^{T} p^{(t)} \cdot m^{(t)} \leq \sum_{t=1}^{T} m_{i}^{(t)} + \eta \sum_{t=1}^{T} |m_{i}^{(t)}| + \frac{\ln n}{\eta}
$$

Thus, for every distribution $p$ we have:

$$
\sum_{t=1}^{T} p^{(t)} \cdot m^{(t)} \leq \sum_{t=1}^{T} p \cdot m^{(t)} + \eta \sum_{t=1}^{T} p \cdot |m^{(t)}| + \frac{\ln n}{\eta}
$$

We choose $p = x^*$.
The Winnow algorithm [Littlestone (1987)]

\[ \sum_{t=1}^{T} p(t) \cdot m(t) \leq \sum_{t=1}^{T} x^* \cdot m(t) + \eta \sum_{t=1}^{T} x^* \cdot \left| m(t) \right| + \frac{\ln n}{\eta} \]

\[ m(t) = \frac{-a_{jt}}{\rho}, \] for some \( j_t \) such that \( a_{jt} \cdot p(t) < 0. \)

\[ \sum_{t=1}^{T} p(t) \cdot \frac{-a_{jt}}{\rho} \leq \sum_{t=1}^{T} x^* \cdot \frac{-a_{jt}}{\rho} + \eta \sum_{t=1}^{T} x^* \cdot \frac{|a_{jt}|}{\rho} + \frac{\ln n}{\eta} \]

\[ 0 < \leq -\frac{\varepsilon T}{\rho} = -2\eta T \leq \eta T \]

\[ \eta T \leq \frac{\ln n}{\eta} \quad \Rightarrow \quad T \leq \frac{\ln n}{\eta^2} = \left(\frac{2\rho}{\varepsilon}\right)^2 \ln n \]
# 0-sum 2-player matrix games

\[
A = \begin{bmatrix}
1 & 0 & 2 \\
3 & 1 & -1 \\
-2 & 4 & 1
\end{bmatrix}
\]

**ROW** chooses a row \(i\).

**COLUMN** chooses a column \(j\).

**ROW** pays **COLUMN** \(A[i,j]\).

\[
2 = \min_i \max_j A[i,j] > \max_j \min_i A[i,j] = 0
\]

No player wants to go first…

Suppose the players play *simultaneously*.

Playing *deterministically* is similar to playing first.

Use *randomized (mixed)* strategies.
0-sum 2-player matrix games

Randomized (mixed) strategy for ROW:
A distribution $p$ over the rows of $A$.

Randomized (mixed) strategy for COLUMN:
A distribution $q$ over the columns of $A$.

If ROW uses $p$ and COLUMN uses $q$, the expected payoff is:

$$A[p, q] = \sum_{i,j} p_i q_j A[i, j] = p^T A q$$
0-sum 2-player matrix games

Von Neumann’s min-max theorem:

\[
\min_p \max_q A[p, q] = \max_q \min_p A[p, q]
\]

\[
\min_p \max_j A[p, j] = \max_i \min_q A[i, q]
\]

\[
\min v \quad \text{s.t.} \quad p^T A \leq v 1^T, \quad p^T 1 = 1, \quad p \geq 0
\]

\[
\max v \quad \text{s.t.} \quad A q \geq v 1, \quad 1^T q = 1, \quad q \geq 0
\]

LP Duality
0-sum 2-player matrix games

\[ A = \begin{bmatrix} 1 & 0 & 2 \\ 3 & 1 & -1 \\ -2 & 4 & 1 \end{bmatrix} \]

ROW chooses a row \( i \).

COLUMN chooses a column \( j \).

ROW pays COLUMN \( A[i, j] \).

\[ 2 = \min_i \max_j A[i, j] > \max_j \min_i A[i, j] = 0 \]

What is the value and what are the optimal strategies?

\[ \begin{bmatrix} 1 & 1 & 1 \\ 3 & 3 & 3 \end{bmatrix} \]

\[ \begin{bmatrix} 6/11 & 1 & 0 & 2 \\ 3/11 & 3 & 1 & -1 \end{bmatrix} \]

\[ \begin{bmatrix} 2/11 & -2 & 4 & 1 \end{bmatrix} \]

value = 1
Solving 0-sum games approximately

Value and optimal strategies can be found by solving an LP. Can be done in polynomial time, but relatively slowly. In many situations a good approximation is sufficient.

W.l.o.g., assume that all entries of $A$ are in $[0,1]$. Let $v^* = val(A)$ be the value of $A$. Let $\epsilon > 0$.

$p$ and $q$ are $\epsilon$-optimal strategies iff:

$$\max_j A[p, j] \leq v^* + \epsilon \quad \min_i A[i, q] \geq v^* - \epsilon$$
0-sum games using Multiplicative Updates
[Freund-Schapire (1999)]

Experts correspond to the $n$ rows of $A$.
A distribution over the experts is a mixed strategy for ROW.

In iteration $t$, the algorithm produces a distribution $p^{(t)}$.
The cost vector $m^{(t)}$ is the column $j^{(t)}$ of $A$ maximizing $A[p^{(t)}, j]$.

Note that $p^{(t)} \cdot m^{(t)} = A[p^{(t)}, j^{(t)}] \geq v^*$.

**Theorem:** If $MW_\eta$ is run with $\eta = \varepsilon/2$ for $T = 4 \ln n / \varepsilon^2$ iterations, then the *best* strategy obtained is $\varepsilon$-optimal for ROW.

If $A$ has $m$ columns, the total running time is $O(\frac{mn \ln n}{\varepsilon^2})$.

An $\varepsilon$-optimal strategy for COLUMN can also be found.
0-sum games using Multiplicative Updates

[Freund-Schapire (1999)]

For any distribution $p$, and in particular $p = p^*$, we have

$$
\sum_{t=1}^{T} A(p^{(t)}, j^{(t)}) \leq (1 + \eta) \sum_{t=1}^{T} A(p^*, j^{(t)}) + \frac{\ln n}{\eta} \leq \nu^* \leq 1
$$

$$
\nu^* \leq \frac{1}{T} \sum_{i=1}^{T} A(p^{(t)}, j^{(t)}) \leq \nu^* + \eta + \frac{\ln n}{\eta T} \leq \nu^* + \epsilon
$$

$$
\eta = \frac{\epsilon}{2}
$$

$$
T = 4 \ln n / \epsilon^2
$$
0-sum games using Multiplicative Updates
[Freund-Schapire (1999)]

\[
\nu^* \leq \frac{1}{T} \sum_{t=1}^{T} A(p^{(t)}, j^{(t)}) \leq \nu^* + \varepsilon
\]

For at least one \( t \) we have:

\[
A(p^{(t)}, j^{(t)}) = \max_j A(p^{(t)}, j) \leq \nu^* + \varepsilon
\]

Thus, if \( t \) minimizes \( A(p^{(t)}, j^{(t)}) \), then \( p^{(t)} \) is \( \varepsilon \)-optimal for \( \text{ROW} \).

\[
(\frac{1}{T} \sum_{t=1}^{T} p^{(t)} \text{ is also } \varepsilon\text{-optimal for } \text{ROW}.)
\]
Let \( q \) be such that
\[
q_j = \frac{\| \{ t \mid j^{(t)} = j \} \|}{T}.
\]
For every \( i \),
\[
\frac{1}{T} \sum_{t=1}^{T} A(i, j^{(t)}) = A(i, q)
\]
\[
\nu^* \leq \frac{1}{T} \sum_{t=1}^{T} A(p^{(t)}, j^{(t)}) \leq (1 + \eta) \frac{1}{T} \sum_{t=1}^{T} A(i, j^{(t)}) + \frac{\ln n}{\eta T}
\]
\[
\leq A(i, q) + \varepsilon
\]
Hence, \( \nu^* - \varepsilon \leq A(i, q) \), for every \( i \), so \( q \) is \( \varepsilon \)-optimal for COLUMN.
Rewards instead of costs

On day $t$ we get a reward vector $r^{(t)}$, instead of a cost vector $m^{(t)}$. Maximize reward instead of minimizing cost.

Simply let $m^{(t)} = -r^{(t)}$.

Multiplicative weight update:

$w_i^{(t+1)} = w_i^{(t)} \left(1 + \eta r_i^{(t)}\right)$

**Theorem:** Assume that $r_i^{(t)} \in [-1, 1]$ and that $0 < \eta \leq \frac{1}{2}$.

Let $p^{(t)}$ be the distribution used by $MW_{\eta}$ at day $t$.

Then, for every $i = 1, 2, \ldots, n$,

$$
\sum_{t=1}^{T} p^{(t)} \cdot r^{(t)} \geq \sum_{t=1}^{T} r_i^{(t)} - \eta \sum_{t=1}^{T} (r_i^{(t)})^2 - \frac{\ln n}{\eta}
$$
Maximum Multicommodity Flow
Maximum Multicommodity Flow

\[ G = (V, E) \] – A directed graph (the flow network)

\[ c: E \to \mathbb{R}^+ \] – A capacity function

\((s_1, t_1), (s_2, t_2), \ldots, (s_k, t_k)\) - \(k\) source-sink pairs.

Maximize the total flow, i.e., the flow sent from \(s_1\) to \(t_1\),

plus the flow sent from \(s_2\) to \(t_2\), etc.

Different commodities can share the edges of the network.

The total flow on an edge should not exceed its capacity.

Exercise: Express the maximum multicommodity flow as a linear program of polynomial size. (Hint: For every edge \(e\) introduce \(k\) flow variables \(f_1(e), f_2(e), \ldots f_k(e)\).
Maximum Multicommodity Flow

We use a different LP formulation of the problem of possibly exponential size (!)

Let $\mathbb{P}$ be the set of simple directed paths from $s_1$ to $t_1$, and from $s_2$ to $t_2$, etc.

For $p \in \mathbb{P}$, let $f_p \geq 0$ be a variable that expresses the flow of the appropriate commodity, on $p$.

We want to maximize $\sum_{p \in \mathbb{P}} f_p$
subject to $f_e = \sum_{p \ni e} f_p \leq c_e$, for every $e \in E$.

$$\max \sum_{p \in \mathbb{P}} f_p$$
$$\text{s.t. } \sum_{p \ni e} f_p \leq c_e, e \in E$$
$$f_p \geq 0, p \in \mathbb{P}$$
Maximum Multicommodity flow

[Garg-Könemman (2007)]

A polynomial time \((1 − \varepsilon)\)-approximation algorithm.

Our presentation follows [Arora-Hazan-Kale (2012)].

Maintain a flow \(f = f^{(t)}\) (may violate the capacity constraints).

Maintain a weight function \(w^{(t)} (\sim p^{(t)})\) on the edges.

Use Multiplicative weight updates with \(\eta = \varepsilon/2\).

In each iteration:

Find a shortest path \(p^{(t)} \in P\) w.r.t. \(w_e^{(t)}/c_e\).

Route \(c^{(t)}\) units of flow on \(p^{(t)}\), where \(c^{(t)} = \min_{e \in p^{(t)}} c_e\).

Define \(r_e^{(t)} = c^{(t)}/c_e \in [0,1]\), if \(e \in p^{(t)}\), and \(r_e^{(t)} = 0\), otherwise.

Let \(f_e\) be the total flow so far on \(e\). Stop when \(\exists e f_e/c_e \geq (\ln m)/\eta^2\).

Down-scale the flow \(f\) to establish all capacity constraints.
Maximum Multicommodity flow
[Garg-Könemman (2007)]

\[
\sum_{t=1}^{T} p(t) \cdot r(t) \geq (1 - \eta) \sum_{t=1}^{T} r_{e}^{(t)} - \frac{\ln m}{\eta}, \quad \forall e \in E
\]

\[
\sum_{t=1}^{T} p(t) \cdot r(t) = \sum_{t=1}^{T} \frac{\sum_{e \in p(t)} w_e^{(t)} \cdot c(e)}{\sum_{e \in E} w_e^{(t)}} = \sum_{t=1}^{T} \frac{\sum_{e \in p(t)} w_e^{(t)} \cdot c(e)}{\sum_{e \in E} w_e^{(t)}}
\]

\[
\leq \frac{1}{F^{opt}} \sum_{t=1}^{T} c(t) = \frac{F}{F^{opt}} \leq 1/F^{opt}
\]

Let \( f^{opt} \) be the optimal flow and let \( F^{opt} = \sum_{p \in \mathcal{P}} f_p^{opt} \)
Maximum Multicommodity flow
[Garg-Könemman (2007)]

Let $f^{opt}$ be the optimal flow and let $F^{opt} = \sum_{p \in \mathbb{P}} f_{p}^{opt}$

Let $w_e$ be arbitrary (non-negative) edge weights.

Let $p \in \mathbb{P}$ be a shortest path w.r.t. edge lengths $w_e/c_e$.

Let $\sum_{e \in E} w_e / \sum_{e \in p} w_e / c_e \geq \sum_{e \in E} w_e \cdot \sum_{p' \ni e} f_{p'}^{opt} / c_e \sum_{e \in p} w_e / c_e \leq 1$

$= \sum_{p' \in \mathbb{P}} f_{p'}^{opt} \sum_{e \in p'} w_e / c_e \sum_{e \in p} w_e / c_e \geq \sum_{p' \in \mathbb{P}} f_{p'}^{opt} = F^{opt}$

$\geq 1$
Maximum Multicommodity flow
[Garg-Könemman (2007)]

\[
\frac{F}{F^{opt}} \geq \sum_{t=1}^{T} p^{(t)} \cdot r^{(t)} \geq (1-\eta) \max_{e} \frac{f_e}{c_e} - \frac{\ln m}{\eta} \geq (1 - 2\eta)C
\]

Maximum congestion = $C$

Upon termination:

\[
C \geq \frac{\ln m}{\eta^2}
\]

Scale down the flow by $C$:

\[
\frac{F}{C} \geq (1 - 2\eta)F^{opt} = (1 - \varepsilon)F^{opt}
\]

$F/C$ is an $(1 - \varepsilon)$-approximate maximal flow!
Maximum Multicommodity flow
[Garg-Könemman (2007)]

How many iterations are needed?

We stop the algorithm when maximum congestion $C \geq \frac{\ln m}{\eta^2}$.

Each iteration adds 1 to the congestion of at least one edge.

Thus, number of iterations is at most $m \left\lfloor \frac{\ln m}{\eta^2} \right\rfloor$.

Total running time is $O \left( \frac{m \ln m}{\epsilon^2} \cdot k \, T_{sp}(m) \right) = \tilde{O} \left( \frac{k \, m^2}{\epsilon^2} \right)$.

[Fleisher (2000)] reduced the running time to $\tilde{O} \left( \frac{m^2}{\epsilon^2} \right)$. 
Positive Semidefinite Programming

\[ \text{max } \mathbf{C} \cdot \mathbf{X} \]
\[ \text{s.t. } \mathbf{A}_j \cdot \mathbf{X} \leq \mathbf{b}_j, \ j \in [m] \]
\[ \mathbf{X} \succeq 0 \]

\[ \mathbf{X}, \mathbf{A}_1, \ldots, \mathbf{A}_m \in \mathbb{R}^{n \times n}, \ \mathbf{b}_1, \ldots, \mathbf{b}_m \in \mathbb{R} \]

\[ \mathbf{A} \cdot \mathbf{B} = \sum_{i,j} \mathbf{a}_{i,j} \mathbf{b}_{i,j} \] (matrix inner product)

\[ \mathbf{A} \succeq 0 \] ((symmetric) positive semidefinite)

\[ \iff \mathbf{x}^T \mathbf{A} \mathbf{x} \geq 0 \text{ for every } \mathbf{x} \in \mathbb{R}^n \]

Can also be approximated using multiplicative updates.

Interesting application:
Approximation algorithm for \textbf{MAX CUT}

“Careful. We don’t want to learn from this.”
(Calvin in Bill Watterson’s “Calvin and Hobbes”)

(Calvin and Hobbes cartoon)
Packing Linear Programs

\[ \begin{align*}
Ax & \leq b \\
x & \in K
\end{align*} \]

Find a feasible \( x \in \mathbb{R}^n \), or show that none exists.

\[ A \in \mathbb{R}^{m \times n}, \quad b \in \mathbb{R}^m, \quad K \subseteq \mathbb{R}^n \] is a “simple” convex set

\[ Ax \geq 0, \text{ for every } x \in K. \quad b > 0 \]

Packing: By scaling, we sometimes assume that \( b = 1 \).

Willing to settle for \( x \in K \) such that \( Ax \leq b + \varepsilon \)

\textbf{ORACLE}: Given a distribution \( p \) on the rows of \( A \), return \( x \in K \) such that \( p^T Ax \leq p^T b \), or “no” if none exists.

If \textbf{ORACLE} returns “no” for any distribution \( p \), then the problem is \textit{infeasible}. 
Packing Linear Programs

\[ A\mathbf{x} \leq \mathbf{b} \quad \text{Find a feasible } \mathbf{x} \in \mathbb{R}^n, \]
\[ \mathbf{x} \in \mathbb{K} \quad \text{or show that none exists.} \]

\[ A \in \mathbb{R}^{m \times n}, \quad \mathbf{b} \in \mathbb{R}^m, \quad \mathbb{K} \subseteq \mathbb{R}^n \text{ is a “simple” convex set} \]

\[ \mathbb{K} \subseteq \mathbb{R}^n \text{ is convex iff } \]
\[ \mathbf{x}, \mathbf{y} \in \mathbb{K}, \ 0 \leq \alpha \leq 1 \quad \Rightarrow \quad (1 - \alpha)\mathbf{x} + \alpha\mathbf{y} \in \mathbb{K} \]

“Simple” is used informally. The only requirement is that ORACLE can be efficiently implemented.

Example: \[ \mathbb{K} = \{ \mathbf{x} \in \mathbb{R}^n : \mathbf{x} \geq 0, \mathbf{c}^T \mathbf{x} = f \} \].
Packing Linear Programs

\[ Ax \leq b \]
\[ x \in K \]

Find a feasible \( x \in \mathbb{R}^n \),
or show that none exists.

\( A \in \mathbb{R}^{m \times n} \), \( b \in \mathbb{R}^m \), \( K \subseteq \mathbb{R}^n \) is a “simple” convex set

**ORACLE**: Given a distribution \( p \) on the rows of \( A \),
return \( x \in K \) such that \( p^T Ax \leq p^T b \), or “no” if none exists.

**ORACLE** is \((1, \rho)\)-bounded iff
for every point \( x \in K \) returned and every \( i \in [m] \),

\[-1 \leq A_i x - b_i \leq \rho \]

This is automatic, \( Ax \geq 0, \ b = 1 \).

The width.
Packing LPs using multiplicative weights
[Plotkin-Shmoys-Tardos (1995)]

Experts correspond to the $m$ linear constraints (rows of $A$). A distribution $p$ corresponds to the constraint $p^T Ax \leq p^T b$. The costs at iteration $t$ are determined by a point $x^{(t)} \in \mathbb{K}$.

$$m^{(t)} = \frac{1}{\rho} \left( b - Ax^{(t)} \right) \in \left[ -1, \frac{1}{\rho} \right]^m$$

Note: Satisfied constraints are more costly.

Use $MW_\eta$ to produce distributions $p^{(1)}, p^{(2)}, \ldots, p^{(T)}$.

In iteration $t$ apply ORACLE to $p^{(t)}$ to obtain $x^{(t)}$ and $m^{(t)}$. If ORACLE returns “no” in any iteration, problem infeasible.

Run for $T = 8\rho \ln m / \varepsilon^2$ and return $\bar{x} = \frac{1}{T} \sum_t x^{(t)}$. 
Packing LPs using multiplicative weights
[Plotkin-Shmoys-Tardos (1995)]

**Theorem:** For any $\varepsilon \geq 0$, after $T = 8\rho \ln m / \varepsilon^2$ iterations of $MW_\eta$, $\eta = \varepsilon / 4$, with an $(1, \rho)$-ORACLE, the point

$$\bar{x} = \frac{1}{T} \sum_t x^{(t)}$$

satisfies $Ax \leq b + \frac{\varepsilon}{1 - \eta}$ and $x \in K$.

As $x^{(t)}$ is the ORACLE’s response to $p^{(t)}$, we have:

$$p^{(t)} \cdot m^{(t)} = \frac{1}{\rho} \left( p^{(t)^T} b - p^{(t)^T} A x^{(t)} \right) \geq 0$$

For every constraint ("expert") $i$ we have:

$$0 \leq \sum_{t=1}^{T} \frac{1}{\rho} (b_i - A_i x^{(t)}) + \eta \sum_{t=1}^{T} \frac{1}{\rho} |b_i - A_i x^{(t)}| + \frac{\ln n}{\eta}$$
Useful fact:

\[
\sum_{t=1}^{T} x_t + \eta \sum_{t=1}^{T} |x_t| = (1 - \eta) \sum_{t=1}^{T} x_t + 2\eta \sum_{t=1}^{T} (x_t)^+
\]

\[(x_t)^+ = \max\{0, x_t\}\]
Packing LPs using multiplicative weights

[Plotkin-Shmoys-Tardos (1995)]

\[
0 \leq \sum_{t=1}^{T} \frac{1}{\rho} (b_i - A_i x^{(t)}) + \eta \sum_{t=1}^{T} \frac{1}{\rho} |b_i - A_i x^{(t)}| + \frac{\ln n}{\eta}
\]

\[
= (1 - \eta) \sum_{t=1}^{T} \frac{1}{\rho} (b_i - A_i x^{(t)}) + 2\eta \sum_{t=1}^{T} \frac{1}{\rho} (b_i - A_i x^{(t)})^+ + \frac{\ln n}{\eta}
\]

\[
\times \frac{\rho}{T}
\]

ORACLE is \((1, \rho)\)-bounded \(\leq 1\)

\[
0 \leq (1 - \eta) \frac{1}{T} \sum_{t=1}^{T} (b_i - A_i x^{(t)}) + 2\eta + \frac{\rho \ln n}{\eta T}
\]

\[
= b_i - A_i \bar{x}
\]

\[
\leq \frac{\varepsilon}{2}
\]

\[
\leq \frac{\varepsilon}{2}
\]
Maximum Multicommodity Flow

\[
\begin{align*}
\max \sum_{p \in \mathcal{P}} f_p \\
\text{s.t. } \frac{1}{c_e} \sum_{p \ni e} f_p & \leq 1, \ e \in E \\
& \quad f_p \geq 0, \ p \in \mathcal{P}
\end{align*}
\]

Using binary search can be essentially reduced to:

Is there a feasible multicommodity flow \( f \) of value \( \sum_{p \in \mathcal{P}} f_p = F \) ?

\[\mathcal{K} = \{ f : f \geq 0, \sum_{p \in \mathcal{P}} f_p = F \} \]

This is now a packing problem.

\textbf{ORACLE} is given a weight \( w_e \geq 0 \) for each edge and has to find a flow \( f \), if there is one, such that

\[
\sum_{e} w_e \frac{1}{c_e} \sum_{p \ni e} f_p \leq \sum_{e} w_e, \quad \sum_{p \in \mathcal{P}} f_p = F
\]

Note: The flow \( f \) returned by \textbf{ORACLE} does not have to satisfy all the capacity constraints. Only one weighted capacity constraint.
Maximum Multicommodity flow

\[ \frac{1}{c_e} \sum_{p \ni e} f_p \leq 1, \ e \in E \]
\[ f \in \mathbb{K} = \{ f : f \geq 0, \sum_{p \in \mathcal{P}} f_p = F \} \]

**ORACLE** is given a weight \( w_e \geq 0 \) for each edge and has to find a flow \( f \), if there is one, such that

\[ \sum_{e} w_e \frac{1}{c_e} \sum_{p \ni e} f_p \leq \sum_{e} w_e , \quad \sum_{p \in \mathcal{P}} f_p = F \]

\[ \sum_{e} w_e \frac{1}{c_e} \sum_{p \ni e} f_p = \sum_{p \in \mathcal{P}} f_p \sum_{e \in p} \frac{w_e}{c_e} \]

Find a path \( p \in \mathcal{P} \) that minimizes \( \sum_{e \in p} \frac{w_e}{c_e} \).

If \( F \sum_{e \in p} \frac{w_e}{c_e} \leq \sum_{e} w_e \), send \( F \) units of flow on \( p \), i.e., \( f_p = F \).

Otherwise, return “no”.

**ORACLE** just needs to solve \( k \) shortest paths problems.
Maximum Multicommodity flow

How good is the algorithm obtained using the framework?

Number of iterations is $T = 8\rho \ln m / \varepsilon^2$

In each iteration, solve $k$ shortest paths problems in $\tilde{\Omega}(mk)$ time.

We also need to multiply by the cost of the binary search.

**ORACLE** is $(1, \rho)$-bounded iff
for every point $\mathbf{x} \in \mathbb{K}$ returned and every $i \in [m]$,  

$$-1 \leq A_i \mathbf{x} - b_i \leq \rho$$

In our case:  

$$\rho \leq \frac{F}{c_{min}} - 1, \text{ where } c_{min} = \min_{e \in E} c_e$$

The running time is $\tilde{\Omega} \left( \frac{F \cdot mk}{\varepsilon^2 c_{min}} \right)$

The running time is not polynomial!
