Scheduling

Problem Description

Motivating example

Scheduling

Problem Description

Definition

- a set of m machines $\{M_1 \dots M_m\}$
- Each event consists of a Job arriving or leaving
- A Job ${\mathcal J}$ consists of a weight w
- The online algorithm is unaware of both future arrivals and departures
- The load of a machine is the total weight of active jobs on the machine.

Scheduling

Problem Description

Summary of Variations

| | Duration | | |
|---|---|--|--|
| Machines | Unknown | Known | Permanent |
| Identical Related Restricted Unrelated | $ \begin{vmatrix} 2 - \frac{1}{m} & [5] \\ \Theta(1) & [7, 6] \\ \Theta(\sqrt{m}) & [6] \\ O(m), \Omega(\frac{m}{\log m}) [1] \end{vmatrix} $ | $ \begin{array}{c} ?\\ \Theta(1)\\ O(\log mT), \Omega(\sqrt{m})\\ O(\log mT), \Omega(\sqrt{m}) \end{array} $ | $\begin{array}{c c} 2-\epsilon \\ \Theta(1) \\ \Theta(\textit{logm}) \\ \Theta(\textit{logm}) \end{array}$ |

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Table: Results for every combination of Machine Model and Job Duration. T is $\frac{\text{largest weight}}{\text{smallest weight}}$. *m* is the number of machines.

Scheduling

Problem Description

Competitive Ratio

Definition

load(m, t) = load on machine m at time t $load_{OPT}(m, t) = algorithm's load for an optimal offline algorithm$ $r = \frac{\max_{t,m} load(m, t)}{\max_{t',m'} load_{OPT}(m', t')}$

Scheduling

Problem Description

Competitive Ratio

Example

Scheduling

Problem Description

Momentary Competitive Ratio

Definition

load(m, t) = largest difference between online and offline $load_{OPT} =$ load for an optimal offline algorithm

$$r = max_t \left(\frac{max_m load(m, t)}{max_{m'} load_{OPT}(m', t)} \right)$$

Scheduling

Problem Description

Momentary Competitive Ratio

Example

Identical machines

Deterministic model

Theorem

There is a $2 - \frac{1}{m}$ competitive algorithm for temporary tasks on identical machines.

◆□ ▶ ◆□ ▶ ◆ □ ▶ ◆ □ ▶ ● □ ● ● ● ●

Identical machines

Deterministic model

Theorem

There is a $2 - \frac{1}{m}$ competitive algorithm for temporary tasks on identical machines.

Lower Bound

Any deterministic online algorithm for load balancing of temporary tasks has competitive ratio of at-least $2 - \frac{1}{m}$.

Identical machines

Deterministic model

Identical machines

Randomized model

Theorem

Any lower bound for the deterministic model where the optimal value of the load is known in advance is also a lower bound on randomized algorithms of the same problem.

Lemma (Yao's theorem)

The lower bound for the competitive ratio of deterministic algorithms on any distribution on the input is also a lower bound for randomized algorithms.

Online Load Balancing of Temporary Jobs Identical machines

Randomized model

Definition

 $T = \{\sigma_1, \dots, \sigma_n\}$ be a set of inputs to a deterministic algorithm D with fixed optimal load.

Consider σ_{worst} , the input corresponding to the worst case cost C_{on} . Then $\sigma_{worst} \in T$.

let S be a random sequence of inputs separated by periods with no active jobs. Then $COST(S) = \max_{\sigma \in S} COST(\sigma)$.

$$P(COST(S) < C_{on}) = P(\sigma_{worst} \notin S) = (1 - \frac{1}{|T|})^{len(S)}$$
$$= (1 - \frac{1}{|T|})^{|T|k}$$
$$\leq e^{-k}$$

Online Load Balancing of Temporary Jobs Identical machines

Randomized model

Definition

 $T = \{\sigma_1, \dots, \sigma_n\}$ be a set of inputs to a deterministic algorithm D with fixed optimal load.

Consider σ_{worst} , the input corresponding to the worst case cost C_{on} . Then $\sigma_{worst} \in T$.

let S be a random sequence of inputs separated by periods with no active jobs. Then $COST(S) = \max_{\sigma \in S} COST(\sigma)$.

$$\mathbb{E}[COST(S)] \ge P(COST(S) < C_{on}) * C_{opt}$$

+ $P(COST(S) = C_{on}) * C_{on}$
= $e^{-k} * C_{opt} + (1 - e^{-k}) * C_{on}$
= $(0) + (1 - 0) * C_{on}$
= C_{on}

Identical machines

Randomized model

Theorem

Any deterministic online algorithm for load balancing of temporary tasks has competitive ratio of at least $2 - \frac{2}{m+1}$ even if the optimal load is known in advance.
