## Motivation

- Mathematical models contain parameters
- Estimating these parameters often involves a least squares (LSQ) minimization, where we want to minimize the sum of squared errors between the model predictions and observations
- If the model is non-linear, this optimization requires gradient information (sensitivities)

## Least Squares Objective Function

$$J(\mathbf{p}) = \sum_{i=1}^{n_o} \sum_{j=1}^{n_y} \frac{\left(\tilde{\mathbf{y}}_j(t_i) - \mathbf{y}_j(t_i, \mathbf{p})\right)^2}{2}$$

•  $\tilde{\mathbf{y}}(t_i) =$  observation at time  $t_i$ 

- **y** $(t_i, \mathbf{p}) =$  model prediction at time  $t_i$
- $\mathbf{y}_j = j^{th}$  state variable
- **p** = vector of unknown parameters
- $n_y =$  number of state variables
- $n_p =$  number of parameters
- $n_o =$  number of observations

・ロト ・ 日 ・ ・ 日 ・ ・ 日 ・ ・ 日

# Least Squares Objective Function

$$J(\mathbf{p}) = \sum_{i=1}^{n_o} \sum_{j=1}^{n_y} \frac{\left(\tilde{\mathbf{y}}_j(t_i) - \mathbf{y}_j(t_i, \mathbf{p})\right)^2}{2}$$

To optimize, we require the sensitivities,  $\frac{\partial J}{\partial \mathbf{p}}$ . The rest of this talk is about numerically approximating  $\frac{\partial J}{\partial \mathbf{p}}$ , for the cases where  $\mathbf{y}(t_i, \mathbf{p})$  satisfies:

- a system of Ordinary Differential Equations (ODEs)
- a system of Delay Differential Equations (DDEs)

### Approximating Sensitivities using Finite Differences (FD)

Standard method for approximating the gradient of a function

$$J_p \approx rac{J(p+\epsilon) - J(p)}{\epsilon} + \mathcal{O}(\epsilon)$$

- Requires J to be computed an additional time for each parameter
- Limited accuracy available, due to numerical issues

### Definitions ODEs

We consider the initial value problem (IVP),

$$\dot{\mathbf{y}}(t) = \mathbf{f}(t, \mathbf{y}(t), \mathbf{p})$$
  
 $\mathbf{y}(0) = \mathbf{y}_0$   
 $t \in (0, T)$ 

# Numerical Solution of ODE IVPs

- Starting from t = 0, advance the solution through time, such that y(t) approximately satisfies the ODE, up to a user specified error tolerance.
- Many numerical schemes exist for doing this
- We use a high order, explicit continuous Runge-Kutta (CRK) solver
- CRK provides a piece-wise continuous polynomial approximation to y(t) over the interval [0, T].

・ロト ・ 日 ・ ・ 日 ・ ・ 日 ・ ・ 日

### Example Solution of an ODE IVP

æ

æ

### Cost of Obtaining $\mathbf{y}(t)$ RK vs CRK

æ

### Variational Method for ODEs

$$\begin{aligned} \frac{d}{dt} \mathbf{y}_{\mathbf{p}}(t) &= \frac{\partial}{\partial \mathbf{p}} \frac{d \mathbf{y}}{dt}(t) \\ &= \frac{\partial}{\partial \mathbf{p}} \mathbf{f}(t, \mathbf{y}(t, \mathbf{p}), \mathbf{p}) \\ &= \mathbf{f}_{\mathbf{y}}(t) \mathbf{y}_{\mathbf{p}}(t) + \mathbf{f}_{\mathbf{p}}(t) \end{aligned}$$

Initial conditions:  $\mathbf{y}_{\mathbf{p}}(0)$ , whose (k, j) entry is,

$$\frac{\partial \mathbf{y}_j}{\partial \mathbf{p}_k}(0) = \begin{cases} 1, & \text{if } \mathbf{p}_k \text{ is the initial condition for } \mathbf{y}_j \\ 0, & \text{otherwise} \end{cases}$$

æ

٠

### Variational Method for ODEs

Solving the Variational Equations, we obtain  $\mathbf{y}_{\mathbf{p}}(t)$ . Then we compute  $J_{\mathbf{p}}$ :

$$J_{\mathbf{p}} = \sum_{i=1}^{n_o} (\tilde{\mathbf{y}}_j(t_i) - \mathbf{y}_j(t_i, \mathbf{p}))^T \mathbf{y}_{\mathbf{p}}(t_i, \mathbf{p})$$

- The system of variational equations is of size nynp
- Directly approximates the **model sensitivities**,  $y_p(t)$

# Least Squares Objective Function

for adjoint method

$$J(\mathbf{p}) = \int_0^T g(s, \mathbf{y}(s, \mathbf{p})) ds$$
$$g(s, \mathbf{y}(s, \mathbf{p})) = \sum_{i=1}^{n_o} \sum_{j=1}^{n_y} \frac{(\tilde{\mathbf{y}}_j(t_i) - \mathbf{y}_j(t_i, \mathbf{p}))^2}{2} \delta(t_i - s)$$

•  $\delta(t_i - s)$  is the Dirac-delta function

æ

ヘロト ヘ週 ト ヘヨト ヘヨト

### Adjoint Method for ODEs

The adjoint vector,  $\boldsymbol{\lambda}^{T}(t)$ , satisfies the IVP,

$$\dot{oldsymbol{\lambda}}^{\mathcal{T}}(t) = g_{oldsymbol{y}}(t) - oldsymbol{\lambda}^{\mathcal{T}}(t) \mathbf{f}_{oldsymbol{y}}(t)$$
 ;  $oldsymbol{\lambda}^{\mathcal{T}}(\mathcal{T}) = oldsymbol{0}$ 

$$J_{\mathbf{p}} = -\int_{0}^{T} \boldsymbol{\lambda}^{T}(t) \mathbf{f}_{\mathbf{p}}(t) dt - \boldsymbol{\lambda}^{T}(0) \mathbf{y}_{\mathbf{p}}(0)$$

See [1] for full derivation

æ

・ロト ・雪 ト ・ ヨ ト ・ ヨ ト

### Adjoint Method for ODEs

The adjoint vector,  $\boldsymbol{\lambda}^{T}(t)$ , satisfies the IVP,

$$\dot{oldsymbol{\lambda}}^{\mathcal{T}}(t) = g_{oldsymbol{y}}(t) - oldsymbol{\lambda}^{\mathcal{T}}(t) oldsymbol{\mathsf{f}}_{oldsymbol{y}}(t)$$
 ;  $oldsymbol{\lambda}^{\mathcal{T}}(\mathcal{T}) = oldsymbol{0}$ 

$$J_{\mathbf{p}} = -\int_{0}^{T} \boldsymbol{\lambda}^{T}(t) \mathbf{f}_{\mathbf{p}}(t) dt - \boldsymbol{\lambda}^{T}(0) \mathbf{y}_{\mathbf{p}}(0)$$

We handle each  $\delta(t_i - t)$ , in  $g_y(t)$ , by forcing the solver to hit  $t = t_i$  and applying the jump:

$$\boldsymbol{\lambda}^{\mathsf{T}}(t_i)^- = \boldsymbol{\lambda}^{\mathsf{T}}(t_i)^+ + (\tilde{\mathbf{y}}(t_i) - \mathbf{y}(t_i, \mathbf{p}))$$

### Definitions DDEs

$$egin{aligned} \dot{\mathbf{y}}(t) &= \mathbf{f}(t, \mathbf{y}(t), \mathbf{y}(t - au_1), \dots, \mathbf{y}(t - au_{n_l}), \mathbf{p}) \ t &\in (0, \, \mathcal{T}) \ \mathbf{y}(t) &= \mathbf{h}(t, \mathbf{p}) \ ; \ t < 0 \end{aligned}$$

 $\mathbf{h}$  is the history function

# Numerical Solution of DDEs

- We use the DDEM package developed by Hossein Zivari Piran
   [3]
- ► To evaluate the lagged values of **y**, we require a continuous approximation to be maintained
- Between discontinuity points, problem reduces to solving an ODE

In the following, we define  $\boldsymbol{\nu} = \mathbf{y}(t - \tau)$ .

(日) (四) (日) (日) (日)

# Example

◆□▶ ◆圖▶ ◆臣▶ ◆臣▶ 三臣.

### Variational Method for DDEs

$$\begin{aligned} \frac{d}{dt} \mathbf{y}_{\mathbf{p}}(t) &= \frac{\partial}{\partial \mathbf{p}} \frac{d \mathbf{y}}{dt}(t) \\ &= \frac{\partial}{\partial \mathbf{p}} \mathbf{f}(t, \mathbf{y}(t, \mathbf{p}), \mathbf{y}(t - \tau, \mathbf{p}), \mathbf{p}) \\ &= \mathbf{f}_{\mathbf{y}}(t) \mathbf{y}_{\mathbf{p}}(t) + \mathbf{f}_{\mathbf{p}}(t) + \mathbf{f}_{\mathbf{\mu}}(t) \mathbf{y}_{\mathbf{p}}(t - \tau) - \mathbf{y}'(t - \tau) \tau_{\mathbf{p}} \end{aligned}$$

- 2

◆□▶ ◆舂▶ ◆臣▶ ◆臣▶

### Adjoint Method for DDEs

$$\dot{\boldsymbol{\lambda}}^{\mathsf{T}}(t) = g_{\mathbf{y}}(t) - \boldsymbol{\lambda}^{\mathsf{T}}(t) \mathbf{f}_{\mathbf{y}}(t) - \frac{\boldsymbol{\lambda}^{\mathsf{T}}(t+ au) \mathbf{f}_{\boldsymbol{
u}}(t+ au)}{\boldsymbol{\lambda}^{\mathsf{T}}(t+ au)}; \boldsymbol{\lambda}^{\mathsf{T}}(t) = \mathbf{0}, ext{for } t \geq \mathcal{T}.$$

$$J_{\mathbf{p}} = -\int_{0}^{T} \boldsymbol{\lambda}^{T}(t) \Big( \mathbf{f}_{\boldsymbol{\nu}}(t) \mathbf{y}'(t-\tau) \alpha_{\mathbf{p}}(t) + \mathbf{f}_{\mathbf{p}}(t) \Big) dt$$
$$-\boldsymbol{\lambda}^{T}(0) \mathbf{y}_{\mathbf{p}}(0) - \int_{-\tau}^{0} \boldsymbol{\lambda}^{T}(t+\tau) \mathbf{f}_{\boldsymbol{\nu}}(t+\tau) \mathbf{h}_{\mathbf{p}}(t) dt$$

See derivation in [4] for a more general class of DDEs

# CheckPointing (Petzold [2])

- Concerned with reducing memory requirements of Adjoint approach
- During forward simulation of the system, store intormation periodically to allow for the forward simulation to be restarted during the backward simulation, as the solution of the forward system is required.
- Alternatively, one could simulate the system in reverse, but it may be unstable

# Summary

- Cost of Adjoint Method scales with the number of observations for LSQ objective functions.
- This cost is due to the observations limiting the step size taken by the solver
- In the case of DDEs, discontinuities in λ(t) make this cost prohibitively expensive.
- Demonstrated use of a lower order method for approximating the adjoint equations and sensitivities for ODEs.
- Demonstrated a continuous approximation to the objective function to reduce the dependence on the number of observations for DDEs.
