

Mutual Exclusion Again

st – status of the process (critical section, or not, or trying)
 other-st – status of the other process
 turn – ensures that they take turns

Model (Cont'd)

```

MODULE prc(other-st, turn, myturn)
VAR
    st : {n, t, c};
    ASSIGN
        init(st) := n;
        next(st) :=

    case
        (st = n) : {t, n};
        (st = t) & (other-st = n) : c;
        (st = t) & (other-st = t)
            & (turn = myturn) : c;
        (st = c) : {c, n};

    1 : st;
    esac;
    next(turn) :=

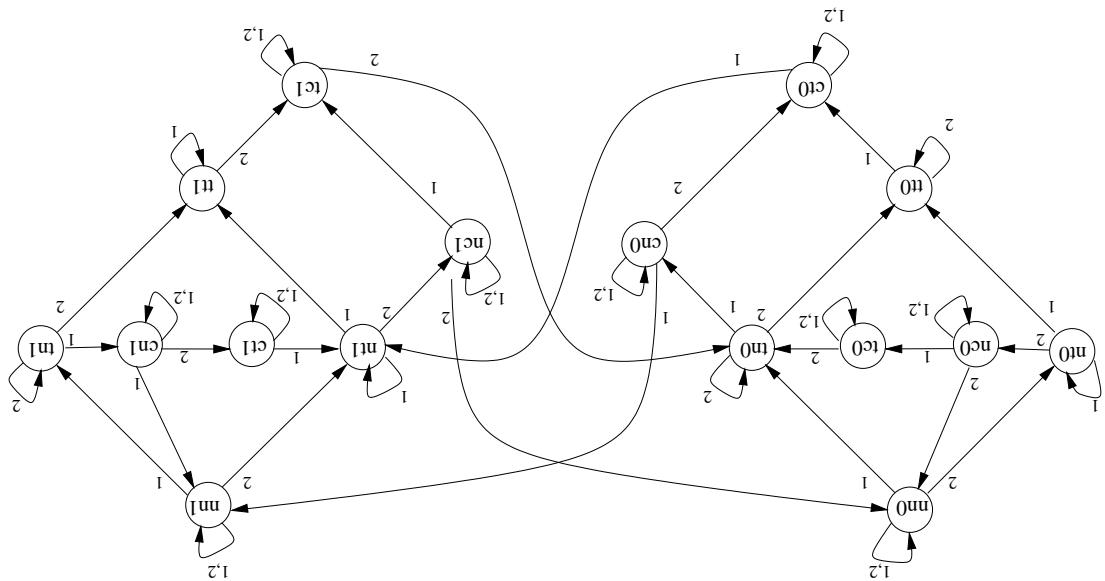

case
    turn = myturn & st = c : !turn;
    1 : turn;
esac;

SPEC AG!((pr1.st = c) & (pr2.st = c))
--liveness
SPEC AG((pr1.st = t) -> AF (pr1.st = c))
SPEC AG((pr2.st = t) -> AF (pr2.st = c))
--no strict sequencing

    (!pr1.st = c &
    E[! pr2.st = c U pr1.st = c ])])
FAIRNESS running
FAIRNESS !(st = c)

```

Comments:

- The labels in the slide above denote the process which can make the move.
- Variable turn was used to differentiate between states s_3 and s_9 , so we now distinguish between ct_0 and ct_1 . But transitions out of them are the same.
- Removed the assumption that the system moves on each tick of the clock. So, the process can get stuck, and thus the fairness constraint.
- In general, what is the difference between the single fairness constraint $\psi_1 \wedge \psi_2 \wedge \dots \wedge \psi_n$ and n fairness constraints $\psi_1, \psi_2, \text{etc.}$, written on separate lines under FAIRNESS?

Notion of Fairness

Fairness: a path p is *fair* w.r.t. property ψ if ψ is true on p infinitely often.

We may want to evaluate A and E constraints only over those paths.

Example: each process will run infinitely often; a process can stay in a critical section arbitrarily long, as long as it eventually leaves.

Two types of fairness: simple

Property ϕ is true infinitely often.

and compound

If ϕ is true infinitely often, then ψ is also true infinitely often.

SMV can deal only with simple fairness.

Formal Definition of Fairness

Let $C = \{\psi_1, \psi_2, \dots, \psi_n\}$ be a set of n fairness constraints. A computation path s_0, s_1, \dots is *fair* w.r.t. C if for each i there are infinitely many j s.t. $s_j \models \psi_i$, that is, each ψ_i is true infinitely often along the path.

We use A_C and E_C for the operators A and E restricted to fair paths.

$E_C U$, $E_C G$ and $E_C X$ form an adequate set.

Also, a path is fair iff any suffix of it is fair.
Finally,

$$E_C[\phi U \psi] = E[\phi U(\psi \wedge E_C G \top)]$$

$$E_C X \phi = EX(\phi \wedge E_C G \top)$$

We only need an algorithm for $E_C G \phi$.

Algorithm for $\mathbb{E}_C G \phi$

- Restrict the graph to states satisfying ψ ; of the resulting graph, we want to know from which states there is a fair path.
- Find the maximal *strongly connected components* (SCCs) of the restricted graph;
- Remove an SCC if, for some ψ_i , it does not contain a state satisfying ψ_i . The resulting SCCs are the fair SCCs. Any state of the restricted graph that can reach one has a fair path from it.
- Use backwards breadth-first searching to find the states on the restricted graph that can reach a fair SCC.

Complexity: $O(n \times |f| \times (S + |R|))$ (still linear in the size of the model and formula).

Guidelines for Modeling with SMV

- Identify inputs from the environment.
- Make sure that the environment is non-deterministic. All constraints on the environment should be carefully justified.
- Determine the states of the system and its outputs. Model them in terms of the environmental inputs.
- Specify fairness criteria, if any. Justify each criterium. Remember that you can over-specify the system. Fairness may not be implementable, and in fact may result in no behaviors.
- Specify correctness in CTL. Comment each CTL property in English.
- Ensure that CTL properties are not satisfied vacuously. That is, each universally-quantified property should be paired up with an existentially-specified property. Also check that LHSs of implications are not always false.

Readings: 6.1-6.3 of Huth, Ryan

Boolean Functions

Boolean functions: $\mathcal{B} = \{0, 1\}$,
 $f : \mathcal{B} \times \cdots \times \mathcal{B} \rightarrow \mathcal{B}$

Boolean expressions:
 $t ::= x \mid 0 \mid 1 \mid \neg t \mid t \wedge t \mid t \vee t \mid t \rightarrow t \mid t \leftarrow t$

Truth assignments: ρ ,
 $[v_1x_1, v_2/x_2, \dots, v_n/x_n]$

Satisfiable: Exists ρ s.t. $t[\rho] = 1$

Tautology: For all ρ , $t[\rho] = 1$

Truth Tables

xyz	$x \rightarrow y, z$	$x_1 \dots x_n$	$f(x_1, \dots, x_n)$
000	0	0 ... 0	1
001	1	0 ... 1	0
010	0	0 ... 1	0
011	1	1 ... 1	0
100	0	1 ... 1	0
101	0	1 ... 1	0
110	1	1 ... 1	0
111	1	1 ... 1	1

2^n entries

What is a good representation of boolean functions?

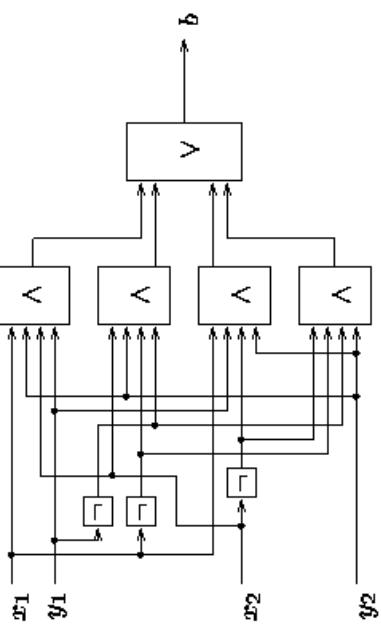

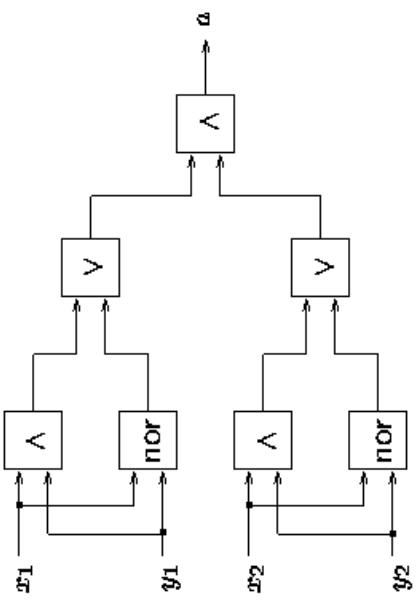

Perfect representation is hopeless:

Theorem 1 (Cook's Theorem)
Satisfiability of Boolean expressions is NP-complete.

(Tautology-checking is co-NP-complete)

Good representations are
compact and
efficient
on real-life examples

Combinatorial circuits

Are these equivalent? Do they represent a tautology? Are they satisfiable?

51

Shannon Expansion

Def: $x \rightarrow y_0, y_1 = (x \wedge y_0) \vee (\neg x \wedge y_1)$

x is the test expression and thus this is an if-then-else.

We can represent all operators using if-then-else on unnegated variables and constants 0(false) and 1(true). This is called INF.

Shannon expansion w.r.t. x :
 $t = x \rightarrow t[1/x], t[0/x]$

Any boolean expression is equivalent to an expression in INF.

52

Example

$t = (x_1 \Leftrightarrow y_1) \wedge (x_2 \Leftrightarrow y_2)$. Represent this in INF form with order x_1, y_1, x_2, y_2 .

- $t = x_1 \rightarrow t_1, t_0$
- $t_0 = y_1 \rightarrow 0, t_{00}$
(since $x_1 = 1, y_1 = 0 \rightarrow t = 0$)
- $t_1 = y_1 \rightarrow t_{11}, 0$
(since $x_1 = 0, y_1 = 1 \rightarrow t = 0$)
- $t_{00} = x_2 \rightarrow t_{001}, t_{000}$
- $t_{11} = x_2 \rightarrow t_{111}, t_{000}$
- $t_{000} = y_2 \rightarrow 0, 1$
 $(x_1 = 0, y_1 = 0, x_2 = 0)$
- $t_{001} = y_2 \rightarrow 1, 0$
 $(x_1 = 0, y_1 = 0, x_2 = 1)$
- $t_{110} = y_2 \rightarrow 0, 1$
 $(x_1 = 1, y_1 = 1, x_2 = 0)$
- $t_{111} = y_2 \rightarrow 1, 0$
 $(x_1 = 1, y_1 = 1, x_2 = 1)$

- - - 0 branch

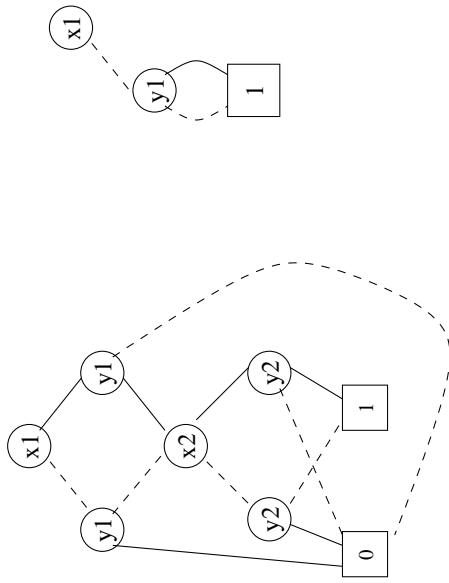

Lots of common subexpressions:

- identify them!

BDDs – directed acyclic graph of Boolean expressions. If the variables occur in the same ordering on all paths from root to leaves, we call this OBDD.

Example OBDD

OBDD for $(x_1 \Leftrightarrow y_1) \wedge (x_2 \Leftrightarrow y_2)$ with ordering $x_1 < y_1 < x_2 < y_2$

ROBDDs

A *Binary Decision Diagram* is a rooted, directed, acyclic graph (V, E) . V contains (up to) two terminal vertices, $0, 1 \in V$. $v \in V \setminus \{0, 1\}$ are non-terminal and have attributes $\text{var}(v)$, and $\text{low}(v)$, $\text{high}(v) \in V$.

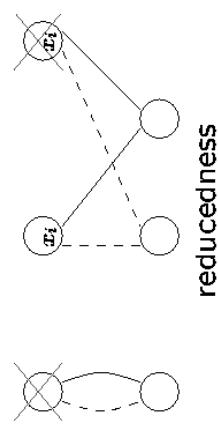

A BDD is *ordered* if on all paths from the root the variables respect a given total order.

A BDD is *reduced* if for all non-terminal vertices u, v ,

- 1) $\text{low}(u) \neq \text{high}(u)$
- 2) $\text{low}(u) = \text{low}(v)$, $\text{high}(u) = \text{high}(v)$, $\text{var}(u) = \text{var}(v)$ implies $u = v$.

If an OBDD does not contain any redundant tests, it is called ROBDD.

ROBDD Examples

Canonicity of ROBDDs

Lemma 1 (Canonicity lemma) For any function $f : \mathcal{B}^n \rightarrow \mathcal{B}$ there is exactly one ROBDD b with variables $x_1 < x_2 < \dots < x_n$ such that $t_b[v_1/x_1, \dots, v_n/x_n] = f(v_1, \dots, v_n)$ for all $(v_1, \dots, v_n) \in \mathcal{B}^n$.

Consequences:

- b is a tautology if and only if $b = \boxed{1}$
- b is satisfiable if and only if $b \neq \boxed{0}$

$$(x_1 \Leftrightarrow x_2) \wedge (x_3 \Leftrightarrow x_4)$$

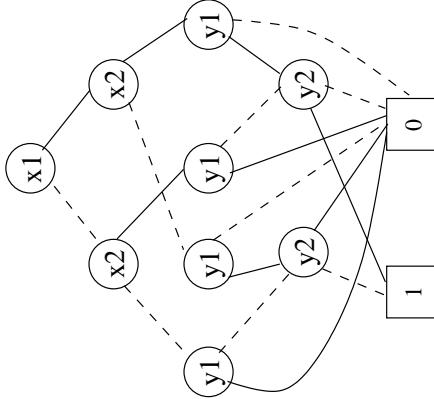

57

58

But...

The size of ROBDD depends significantly on the chosen variable ordering!

Example: ROBDD for $(x_1 \Leftrightarrow y_1) \wedge (x_2 \Leftrightarrow y_2)$ with ordering $x_1 < x_2 < y_1 < y_2$

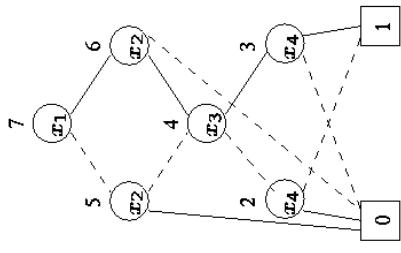

Under ordering $x_1 < y_1 < x_2 < y_2$ had 6 nodes.

Furthermore...

- The size according to one ordering may be exponentially smaller than another ordering.
- Figuring out the optimal ordering of variables is co-NP-complete.
- Some functions have small size independent of ordering, e.g. parity.
- Some functions have large size independent of ordering, e.g., multiplication

Implementing BDDs

```
{root: integer; var, low, high: array of integer;}
```

	var	low	high
0	?	?	?
1	?	?	?
2	4	1	0
3	4	0	1
4	3	2	3
5	2	4	0
6	2	0	4
7	1	5	6

Helper Functions: Makemode and Hashing

Makemode ensures reducedness using a hash table

$$H : (i, l, h) \rightarrow u$$

```

Makemode( $H$ ,  $\max$ ,  $b$ ,  $i$ ,  $l$ ,  $h$ )
1: if  $l = h$  then return  $l$ 
2: else if  $member(H, i, l, h)$ 
3:   then return  $lookup(H, i, l, h)$ 
4: else  $max \leftarrow max + 1$ 
5:    $b.var(max) \leftarrow i$ 
6:    $b.low(max) \leftarrow l$ 
7:    $b.high(max) \leftarrow h$ 
8:    $insert(H, i, l, h, max)$ 
9: return  $max$ 

```

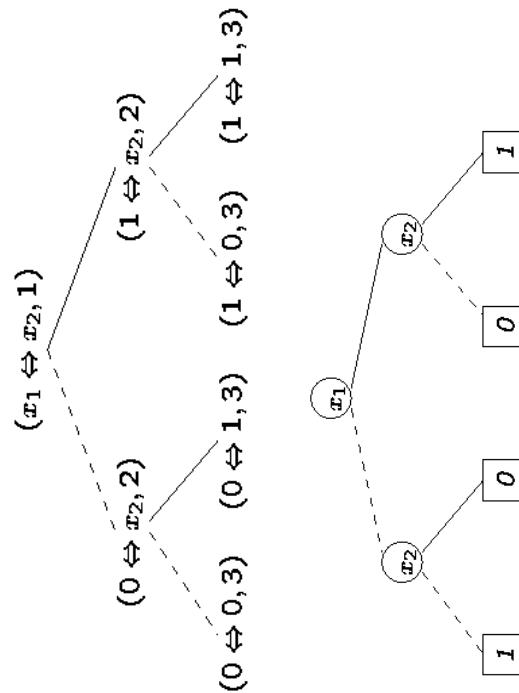

61

62

Build

Build: Maps a Boolean expression t into an ROBDD.

Build Example

```
function Build(t)
1:   H ← emptytable; max ← 1
2:   b.root ← build'(t, 1)
3:   return b

function build'(t, i)
1:   if  $i > n$  then
2:     if  $t$  is false then return 0
3:     else return 1
4:   else  $l \leftarrow build'(t[0/x_i], i + 1)$ 
5:      $h \leftarrow build'(t[1/x_i], i + 1)$ 
6:     return makenode(H, max, b, i, l, h)
```

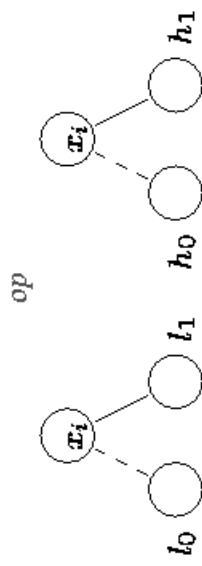

63

64

Boolean Operations on ROBDDs

Ordering: $x_1 < \dots < x_n$

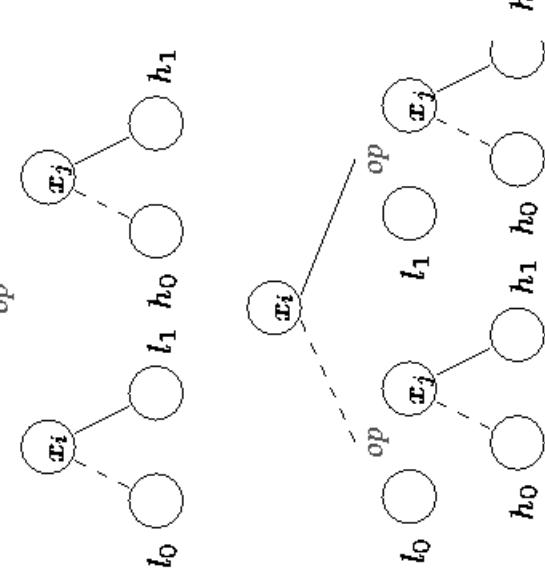

$$(x_i \rightarrow l_1, l_0) \text{ op } (x_i \rightarrow h_1, h_0) = \\ x_i \rightarrow (l_1 \text{ op } h_1), (l_0 \text{ op } h_0)$$

Boolean Operations on ROBDDs(Cont'd)

If $x_i < x_j$:

$$(x_i \rightarrow l_1, l_0) \text{ op } (x_j \rightarrow h_1, h_0) = \\ x_i \rightarrow (l_1 \text{ op } (x_j \rightarrow h_1, h_0)), \\ (l_0 \text{ op } (x_j \rightarrow h_1, h_0))$$

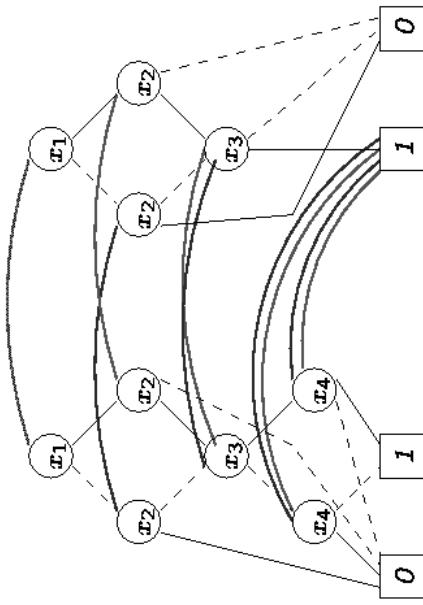

65

66

Function Apply

Used to perform operations on two ROBDDs.

Example:

Can be either recursive or using dynamic programming.

Other Operations on ROBDDs

Restrict – $b[v/x]$

given a truth assignment for x , compute ROBDD for b

Example:

Size – $\text{size}(b) = |\{\rho \mid b[\rho] = 1\}|$

”number of valid truth assignments”

Anysat – $\text{anysat}(b) = \rho$, for some ρ with $b[\rho] = 1$

”give a satisfying assignment”

Compose – $\text{compose}(b, x, b') = b[x/b']$

”substitute b' for all free occurrences of x ”

Existential quantification – $\exists x.b = b[x/0] \vee b[x/1]$

Using dynamic hash-table implementation, can get amortized cost for operations to be $O(1)$.

Representing Boolean Functions
