Lecture 13: Virtual Memory Management

CSC 469H1F / CSC2208H1F
Fall 2007
Angela Demke Brown
Topics

- Review virtual memory basics
- Large (64-bit) virtual address spaces
- Multiple Page Sizes (Wednesday)
- Next Week
  - Placement policy and cache effects
  - NUMA multiprocessor memory management
  - Distributed shared memory
Memory Management Requirements

- **Relocation**
  - Programmers don’t know what physical memory will be available when their programs run
  - \(\rightarrow\) need some type of address translation

- **Protection**
  - A process’s memory should be protected from *unwanted access* by other processes, both intentional and accidental
  - \(\rightarrow\) Requires hardware support

- **Sharing**
  - Need ways to specify and control what sharing is allowed

- **Logical/Physical Organization**
  - Map between program structures and linear array of bytes
  - Manage transfers between disk and main memory
Virtual address space

- process address space (A.S.) layout
  - logical or virtual A.S.
- CPU generates logical addresses in this space as program executes
  - Called virtual addresses
- Memory system must see physical (real) addr
  - Translation is done by memory management unit (MMU)
  - Physical memory must be allocated for each virtual location used by the program
Paging

- Partition memory into equal, fixed-size chunks
  - called *page frames* or simply *frames*
- Divide processes’ memory into chunks of the same size
  - These are called *pages*
- Any page can be assigned to any free page frame
  - No external fragmentation
  - Minimal internal fragmentation
- First seen in CTSS circa 1961
- *Demand paging* (automatic transfer to/from backing store) first used in the Atlas computer
  - Described in a 2-page CACM article, 1961
Atlas virtual memory

• Inverted page table (entry per physical page, records what virtual page is stored there)
  • Only 2048 entries, stored in registers, searched in parallel
• Missing pages fetched on demand from drum into core
  • Victim also selected on demand
"Typical" Address Translation

Virtual Address

Page number

Physical Memory
Page tables - space limitations

- Memory required for page table can be large
  - Need one PTE per page
  - 32 bit virtual address space w/ 4K pages = $2^{20}$ PTEs
  - 4 bytes/PTE = 4MB/page table
  - 25 processes = 100MB just for page tables!
- Solution 1: Hierarchical page tables
  - Aka forward-mapped page tables
64-bit address spaces

- Suppose we just extended the hierarchical page tables with more levels
  - 4K pages → 52 bits for page numbers
  - Maximum 512 8-byte entries per level → 6 levels
    - Too much overhead
  - 16K pages → 48 bits for page numbers
  - Maximum 2048 entries per level → 5 levels
    - Not that much better
- “A new page table for 64-bit address spaces”, Talluri, Hill & Khalidi, SOSP ’95
  - Introduces clustered page tables, building on the concept of hashed page tables
Recall Hashed Page Tables

- Hash function maps virtual page number (VPN) to bucket in fixed-size hash table
- Search entries at that bucket for matching VPN
Hashed Page Tables

- Hash table should have 1 bucket per physical page to keep expected chain length short
  - Overhead is fixed, good for sparse address spaces
  - Overhead is high (200%, or 16 bytes for 8 bytes of mapping info)
    - Next field can be eliminated with fixed number of PTEs per bucket (PowerPC)
    - Need mechanism to handle overflow in this case

- Want fixed, low overhead for both sparse and dense address spaces
Clustered page tables

- Similar to hashed page tables
  - But each entry stores mapping information for several consecutive pages with a single key
- Hashed page tables with subblocking
Clustered Page Tables

✓ Less overhead than hashed page tables
  • E.g. subblock factor 16, 18 64-bit words → 144 bytes per clustered PTE
  • Break even if 6 mappings used (same overhead as hashed p.t.)
    • Roughly 1/3 less space if all mappings used
      ✗ Can use more space if address space is very sparse
        • Use smaller subblock factor
✓ Smaller hash table or shorter chains → more efficient access
  ✗ But can be worse if PTEs span multiple cache lines
Page tables - time overhead

- Each virtual memory reference requires multiple physical memory references to complete
  - 1 per level in hierarchical tables + actual data access
- Solution: cache recently used translations in MMU
  - Translation lookaside buffer (TLB)
  - Fully associative cache (all entries looked up in parallel)
  - Indexed by virtual page numbers
  - entries are PTEs (entries from page tables)
  - With PTE + offset, can directly calculate physical address
TLB performance

- TLB hit rates critical to performance
  - $TLB \text{ reach} =$ fraction of the virtual address space covered by the TLB
  - Depends on page size, number of TLB entries
- TLB size is fixed (typically small, 2048 entries or less)
  - 4 KB page $\rightarrow$ TLB reach is $2048 \times 4K = 8$ MB
  - 16 KB page $\rightarrow$ TLB reach is 64 MB
  - Miniscule compared to data sets used by applications today
- Just using a larger page size for everything is problematic
  - Internal fragmentation
- Solution: support multiple page sizes
Superpage TLBs

- **Superpages**: page sizes are power-of-two multiples of the base page size
  - Must be aligned in both virtual and physical memory (e.g. 4 MB superpage must begin on a 4 MB address boundary in both spaces)

- TLB entry (copy of PTE) includes page size
- Supported by MMU’s in many processors
  - MIPS, UltraSPARC, Alpha, PowerPC ...
  - Itanium II sizes: 4K, 8K, 16K, 64K, 256K, 1M, 4M, 16M, 64M, 256M, 1G, 4G
Subblock TLBs

- **Subblocking** associates multiple physical page numbers (PPN) with each TLB tag
  - TLB tag is Virtual page block number (VPBN)
  - Subblocks must be aligned in virtual address space, but each virtual page has a separate PPN so they need not be aligned in physical space
  - Supported by MIPS R4x00 processors (subblock factor of 2)
  - Increases size of TLB entry vs. superpages

- **Partial subblocking** blends ideas
  - TLB entry stores only one PPN, but multiple valid bits
  - Subblocks must be aligned, but not all pages must be valid
