Let $f$ and $g$ be functions from $\text{nat}$ to $\text{nat}$.

(a) For what $f$ do we have the theorem $f g = g$?

Equality $f g = g$ means, first, that the domains are equal.

\[
\begin{align*}
\square (f g) &= \square g \\
\equiv & \quad (\forall x: \text{nat} \cdot g x: \square f) = \square g \\
\equiv & \quad (\forall x: \text{nat} \cdot g x: \text{nat}) = \text{nat} \\
\equiv & \quad (\forall x: \text{nat} \cdot \top) = \text{nat} \\
\equiv & \quad \text{nat} = \text{nat} \\
\equiv & \quad \top
\end{align*}
\]

so that's no constraint. Equality also means that the results are equal.

\[
\begin{align*}
\forall x: \text{nat} \cdot (f g) x &= g x \\
\equiv & \quad \forall x: \text{nat} \cdot f (g x) = g x
\end{align*}
\]

So $f$ must be the identity function on the range of $g$.

\[
\forall x: \text{nat} \cdot f x = x
\]

(b) For what $f$ do we have the theorem $g f = g$?

The domains of $g f$ and $g$ must be equal, and they are both $\text{nat}$. The results must also be equal.

\[
\begin{align*}
\forall x: \text{nat} \cdot (g f) x &= g x \\
\equiv & \quad \forall x: \text{nat} \cdot g (f x) = g x
\end{align*}
\]

For any $x$ such that $f x \neq x$, $g$ must give the same result for both $f x$ and $x$. If $f$ is the identity function, then $g f = g$. If $g$ is a constant function, then $g f = g$.
