- Make sure your examination booklet has 13 pages (not including this one).
- Write your answers in the spaces provided. Do not feel that you must use all of the space provided. If you run out of space on any question, use the back of a page, and draw an arrow to point this out.
- You will be rewarded for answers that are concise and well thought out, rather than long and rambling.
- Write legibly. Unreadable answers will be given 0.
- When asked to write code, comments are not necessary.

*Good Luck!*
Question 1
[12 marks in total]

(a) [2 marks]
Write your name and student number legibly at the top of every page of this exam.

(b) [2 marks]
Suppose you have an array A which you wish to treat as “circular”, and an index i into that array. Complete the following line of code so that it advances i to the “next” position in the circular array.

\[ i = \]

(c) [2 marks]
Here is a binary tree:

```
       b
      /\  
     a  c  
    /   \  
   d     e  f  
  / \   / \  
 g  h  
```

Circle one answer to complete the following inorder traversal of this tree: a b c ...

1. ... d a e g e h f c
2. ... g e h d a e f c
3. ... d e f g h
4. ... g h d e f
5. The sequence cannot be completed to form an inorder traversal of this tree.

(d) [2 marks]
Give a preorder traversal for the same tree:

(e) [4 marks]
Assume that you have a tree, represented using nodes and references. For each of the following operations, circle one answer to indicate whether it can be done elegantly without recursion (i.e., without having to build your own stack), or whether it needs recursion to be done elegantly.

<table>
<thead>
<tr>
<th>Operation</th>
<th>Elegant without recursion</th>
<th>Needs recursion</th>
</tr>

Question 2
[6 marks in total]

Consider the following method, and the BTNode class it uses. Note that Math.max(a, b) returns
the maximum of a and b.

// Pre-condition: All nodes in the tree
// rooted at r contain Integers.
public static int mystery(BTNode r) {
    if (r == null)
        return 0;
    else {
        class BTNode {
            public Object data;
            public BTNode left, right;
        }
        int left = mystery(r.left);
        int right = mystery(r.right);
        return Math.max(left, right) + ((Integer)r.data).intValue();
    }
}

(a) [2 marks]
What value is returned if we call mystery with a reference to the root of this binary tree:

```
     3
    / \
   21  5
  /   / \
 3    14  20
```

Answer:

(b) [2 marks]
How many calls to mystery occur, in total, as a result of that initial call to mystery?

Answer:

(c) [2 marks]
Write an appropriate comment that describes what mystery returns.
Question 3
[16 marks in total]

For each of the following methods, write an appropriate pre-condition and post-condition, or write “none” if there is none. Don’t bother stating pre-conditions that are enforced by the compiler. For example, for an int parameter, you don’t need to say “i must be an integer”.

(a) [4 marks]

    // Pre-condition:

    // Post-condition:

    public static void sneezy (int[] A, int n, int v) {
        for (int i=0; i<n; i++)
            A[i] = v;
    }

(b) [4 marks]

    // Pre-condition:

    // Post-condition:

    public static int happy (Node p) {
        Node temp = p.next;
        int n = 1;
        while (temp != p) {
            n++;
            temp = temp.next;
        }
        return n;
    }

Continued
(c) [4 marks]

    // Pre-condition:

    // Post-condition:

    public static int sleepy (int[] A, int n) {
        for (int i=0; i<A.length; i++) {
            if (A[i] == n)
                return i;
        }
        return -1;
    }

(d) [4 marks]

    // Pre-condition:

    // Post-condition:

    public static int bashful (int[] A, int n) {
        int i = A.length-1;
        while (A[i] != n)
            i--;
        return i;
    }
Question 4
[14 marks in total]

Consider the following ADT: A sequence is a container that holds items. It has no fixed size, and any position in which no value has been stored is considered to contain null. The operations that can be performed on a sequence are:

- set(i, item): sets the i\(^{th}\) position of the sequence to item.
- get(i): returns the value in the i\(^{th}\) position of the sequence, or null if nothing has been stored at that position.

The positions in a sequence are counted from zero. Thus, the first position is position zero. Here is a Java interface for sequences:

```java
interface Sequence {
    // Sets the i-th position of the sequence to item.
    public void set (int i, Object item);

    // Returns the value in the i-th position of the sequence, or
    // null if nothing has been stored at that position.
    public Object get (int i);
}
```

(a) [5 marks]
Suppose we have a class called LinkedSequence that implements Sequence. Complete the following method, which is to go outside the LinkedSequence class. It should return the item just before the first null value in seq, or null if the first position of the sequence holds the value null.

```java
public static Object beforeNull (LinkedSequence seq) {
    // Your implementation here
}
```

Continued
Suppose class `LinkedSequence` implements `Sequence` using a singly-linked list. It begins with an empty linked list, and adds new nodes on the end whenever necessitated by the `set` method. Below is an outline for the class, as well as the `Node` class that it uses:

class LinkedSequence implements Sequence {
    // The first node in the linked list.
    // Contains the first element of the sequence.
    private Node first;

    // Methods would go here.
}

(b) [5 marks]
Write the `get` method for class `LinkedSequence`. Do not add any instance variables to class `LinkedSequence`.

    // Returns the value in the i-th position of the sequence, or
    // null if no object has been stored at that position.
    public Object get (int i) {

Continued
(c) [2 marks]
Given what you now know about class `LinkedSequence`, what is the worst-case big-oh time complexity of your `beforeNull` method? Make sure you define any variables that you use.
You can answer this question even if you haven't solved part (a) or (b).

**Answer:**

(d) [2 marks]
Suppose the `beforeNull` method were to go inside class `LinkedSequence` instead of outside. This would allow us to write a faster version of the method. What would the worst-case big-oh time complexity of the method be? Make sure you define any variables that you use. Do not assume the existence of any instance variables other than `first`.

**Answer:**
Question 5
[14 marks in total]

(a) [2 marks]
Write a fragment of code that takes $O(n^2)$ time but not $O(n)$ time.

(b) [2 marks]
Write a loop that takes $O(1)$ time.

(c) [2 marks each]
What is the worst-case big-oh time complexity of each of the following problems? Assume that the problems are solved efficiently and that there are no restrictions on the algorithms that may be used.

Search an unsorted array of $n$ elements for a given value.
   **Answer:**

Search a sorted linked list of $n$ elements for a given value.
   **Answer:**

Search a binary search tree with $n$ nodes for a given value.
   **Answer:**

Determine whether or not a sorted array of $n$ elements has any duplicate values.
   **Answer:**

Determine whether or not an unsorted array of $n$ elements has any duplicate values.
   **Answer:**

Continued
Question 6
[7 marks in total]

Consider the following method:

```java
public static int huh( int[] A, int start, int finish ) {
    System.out.println("Range: " + start + " " + finish);
    int ans;
    if (start == finish)
        ans = A[start];
    else {
        int middle = (start + finish) / 2;
        int one = huh(A, start, middle);
        int two = huh(A, middle+1, finish);
        System.out.println("Results: " + one + " " + two);
        ans = Math.max( one, two);
    }
    System.out.println("Ans: " + ans);
    return ans;
}
```

Assume that we have an array A of size 4, as shown below. What would be the output if we called huh(A, 0, 3)?

```
<table>
<thead>
<tr>
<th></th>
<th>98</th>
<th>4</th>
<th>222</th>
<th>-1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>2</td>
<td>3</td>
<td></td>
</tr>
</tbody>
</table>
```
Question 7
[8 marks in total]

Suppose we have a binary tree in which each leaf stores a `Double` and each internal node stores an operator, either `+` or `*` (represented as a `String`). Such a tree can represent simple arithmetic expressions. For example, the following tree represents the expression \((3 + (((4 * (6 + 8)) * (25 + 2)))\):

```
          +
         / \
        3   *
       /   / \
      *   +   2
     / \
    4   25
   /   \
   6    8
```

Complete the following method for computing the value of an expression represented by such a tree. It uses the same `BTNode` class as on page 2.

```java
    // Pre-condition: root is not null, every leaf in the tree is a Double,
    // and every internal node contains either "+" or "*".
    public static Double value( BTNode root ) {
```
**Question 8**
[14 marks in total]

A **full** binary tree is one in which every node except the leaves has exactly two children, and all leaves are on the same level. Examples:

Three trees that are full: Two trees that are not full:

Recall that the height of a tree is the number of nodes on the longest path from the root to a leaf.

(a) [2 marks]
Suppose we were going to prove that for all \( h \geq 1 \), a full binary tree of height \( h \) has \( 2^h - 1 \) nodes. Would it be best to use weak or strong induction? Circle one.

\[ \text{weak} \quad \text{strong} \]

Explain why. Be specific.

(b) [8 marks]
Now do the proof. Write your proof on the next page.

(c) [2 marks]
Suppose we have a full binary tree with \( n \) nodes. What can you assert about the value of \( n \)?

(d) [2 marks]
How many leaves does a full binary tree with \( n \) nodes have?
Proof for part (b):

Prove: For all \( h \geq 1 \), a full binary tree of height \( h \) has \( 2^h - 1 \) nodes.
Question 9
[9 marks in total]

Here are interfaces for Stack and Queue:

```java
public interface Queue {
    // Append o to me.
    public void enqueue(Object o)
        throws QueueFullException;
    // Remove and return my first Object.
    public Object dequeue();
        throws QueueEmptyException;
    // Return true if I am empty.
    public boolean isEmpty();
}
```

```java
public interface Stack {
    // Push o onto me.
    public void push(Object o)
        throws StackFullException;
    // Pop off my top object and return it.
    public Object pop();
        throws StackEmptyException;
    // Return true if I am empty.
    public boolean isEmpty();
}
```

Write a non-recursive method to print a linked list in reverse order. Its only parameter should be the first Node in the linked list. Use the Node class on page 6.

Assume that you have a class MyStack that implements Stack, and a class MyQueue that implements Queue. You may find these classes to be useful in your solution. You need not catch any exceptions that are thrown.
