OODBMS

- Object-Oriented DBMS (OODBMS) are DBMS which are based on an Object-Oriented Data Model.
- Such data models are often inspited by OO programming languages, such as SmallTalk or C++.
- OODBMS are capable of storing complex objects, l.e., objects that are composed of other objects, and/or multi-valued attributes
- The great advantage of OODBMS is that it is not necessary to transform the UML classes into a logical schema (e.g., relational).
- Their main disadvantage is that their technology is immature and they are only used in niche applications, such as CAD.

OODBMS vs RDBMS

- RDBMS have been around for more than 20 years, OODBMS are relatively new:
- RDBMS can handle >10¹⁰ records, OODBMS up to 10⁷
- OODBM good for storing complex descriptions (e.g., a plant schematic), RDMSs appropriate for simple, "flat" data.
- RDBMS control the DB market (>90%), OODBMS own <5% of the market.
- Most commercial RDBMS come with an "Object-Relational" extension which implements an object database on top of a RDBMS.

Object Database Standard

- Object Data Management Group has set a standard for Object Databases (version 3.0).
 - ODL Object Definition Language
 - OML Object Manipulation Language
- However, individual ODBMS do not necessarily conform to the standard (...usual story...)

ObjectStore PSE: An OODBMS

- ObjectStore PSE (Persistent Storage Engine):
 - provides persistence for Java programs;
 - builds navigational structure into the database;
 - requires all persistent objects to be instances of subclasses of COM.odi.Persistent;
- ObjectStore provides full OODBMS functionality.

Distributed Information Systems

- Most information systems are distributed.
- This means that the objects that participate in a particular use case need not be on the same machine with other objects and users they are supposed to interact.
- One can use Remote Procedure Calls-RPC (C/C++) and Remote Method Invocation-RMI (Java).
- The object-oriented industrial standard for distributed objects is CORBA (Common Object Request Broker Architecture)

© 2002 Jaelson Castro and John Mylopoulo

OO Database Design

CORBA CORBA separates the interface of a class from its implementation.

- The implementation runs on one machine, the interface can be compiled on several other machines.
- When accessed by a client program, an object is treated as though it is in memory on the client machine; however, the object may actually be located on another machine.
- When the client program sends an object a message to invoke one of its operations, the message and parameters are converted into a format that can be sent over the network (*marshalling*)
- At the other end, the server unmarshals the data back into a message with arguments, and passes these on to the implementation of the target object.
- CORBA achieves this by means of programs known as ORBs (Object Request Brokers) that run on each machine.
- The ORBs communicate with each other by means of an Inter-ORB Protocol (IOP).
- Over the Internet, the protocol used is IIOP (Internet IOP)

Designing Data Management Classes

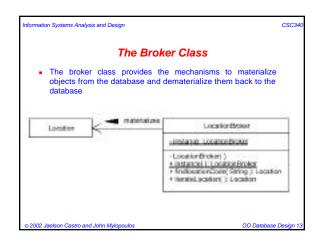

- Idea is to not use a DBMS (Relational or Object-Oriented.)
- Instead,design data management classes which handle persistence, caching, etc.
- These classes decouple applications from their persistent
- Use data management classes whenever you need to:
 - Store an application object;
 - Search for or retrieve stored objects;
 - Interface with an external database.
- This solution won't work for large data sets!

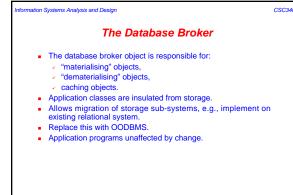

CSC34

rmation Systems Analysis and Design Data Storage Layer Options for locating the operations that handle the tasks of storing and retrieving objects: All persistent objects in the system could inherit methods for storage from an abstract superclass - PersistentObject Introduce separate classes into the system whose role is to deal with the storage and retrieval of other classes (Database broker approach)

PersistentObject Superclass Approach A superclass PersistentObject encapsulates the mechanisms for an object of any class to store itself in, or retrieve itself from a database. This superclass implements operations to get an object by object identifier, store, delete and update objects and to iterate through a set of objects (write and read operations).

nformation Systems Analysis and Design **PersistentObject** formation Systems Analysis and Design **Database Broker Approach** • Each persistent class could be responsible for its own storage... ...but. highly coupled (to storage mechanism); lessens class cohesion: class must now have expert knowledge of storage tasks; these are unrelated to application tasks. Solution: indirection (add a go-between). Separates the business objects from their data storage implementation. The classes that provide the data storage services will be held in a separate package. For each business class that needs to be persistent, there will be an associated database broker class.

ation Systems Analysis and Design **Caching Objects** • Objects can be cached for efficiency. • The cache is a collection maintained by the database broker. When an object is requested, the cache is searched first. If the object sought is not in the cache it is materialised by the database broker from the database 02 Jaelson Castro and John Mylopo

Transaction Management To manage transactions, we need to keep track of all changes made by a transaction, in case the transaction is aborted before it completes execution (and commits all its changes.) Multiple caches can be used for transaction management: new clean cache: newly created objects new dirty cache: newly created objects that have been amended new delete objects: newly created objects that have been deleted old clean cache: objects retrieved from the database old dirty cache: retrieved objects that have been ammended
 old delete objects: retrieved objects that have been deleted

nformation Systems Analysis and Design CSC34 **Collections** • In systems where collection classes are used in design, these may be replaced by database broker objects. Database objects provide collection-like services for large volumes of data (more than you would maintain in a collection class in memory).
