The Entity-Relationship Model -- 1

Information Systems Analysis and Design

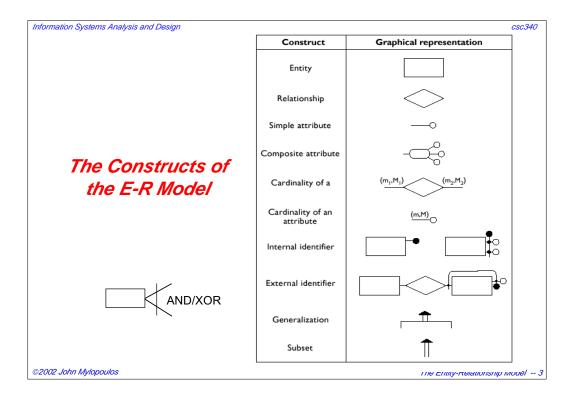

csc340

The Entity Relationship Model

- The *Entity-Relationship* (ER) *model* is a *conceptual* data model, capable of describing the data requirements for a new information system in a direct and easy to understand graphical notation.
- Data requirements are described in terms of a conceptual (or, ER) schema.
- ER schemata are comparable to class diagrams.

©2002 John Mylopoulos

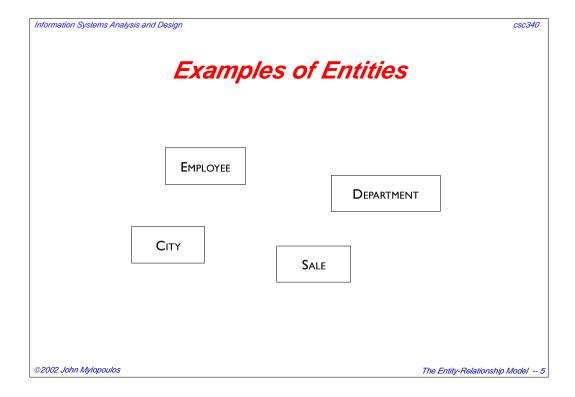

csc340

Entities

- These represent classes of objects (facts, things, people,...) that have properties in common and an autonomous existence.
- City, Department, Employee, Purchase and Sale are examples of entities for a commercial organization.
- An instance of an entity is an object in the class represented by the entity.
- Stockholm, Helsinki, are examples of instances of the entity City, and the employees Peterson and Johanson are examples of instances of the Employee entity.
- The E-R model is very different from the relational model in which it is not possible to represent an object without knowing its properties (an employee is represented by a tuple containing the name, surname, age, and other attributes.)

©2002 John Mylopoulos

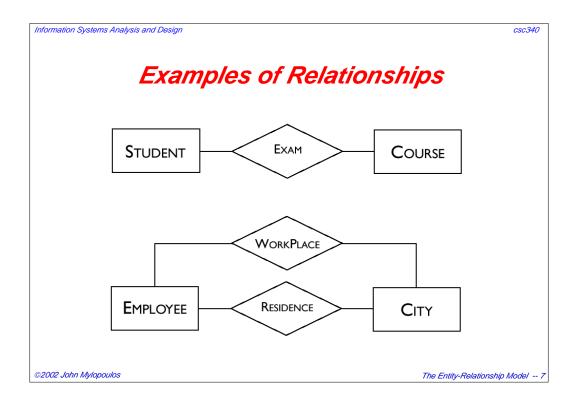

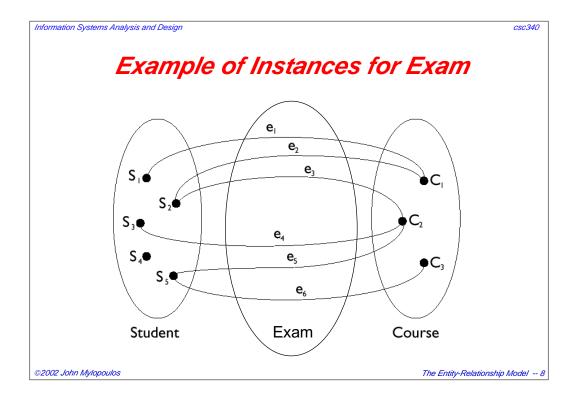

csc340

Relationships

- They represent logical links between two or more entities.
- Residence is an example of a relationship that can exist between the entities City and Employee; Exam is an example of a relationship that can exist between the entities Student and Course.
- An instance of a relationship is an n-tuple made up of instances of entities, one for each of the entities involved.
- The pair (Johanssen,Stockholm), or the pair (Peterson,Oslo), are examples of instances in the relationship Residence.

©2002 John Mylopoulos

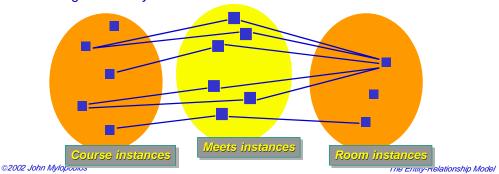

csc340

csc340

What Does An E-R Diagram Really Mean?

- Course and Room are entities. Their instances describe particular courses (e.g., CSC340S) and particular rooms (e.g., WB116).
- Meets is a relationship. Its instances describe particular meetings. Each meeting has exactly one associated course and room

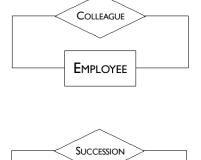

Recursive Relationships

Recursive relationships are also possible, that is relationships between an entity and itself.

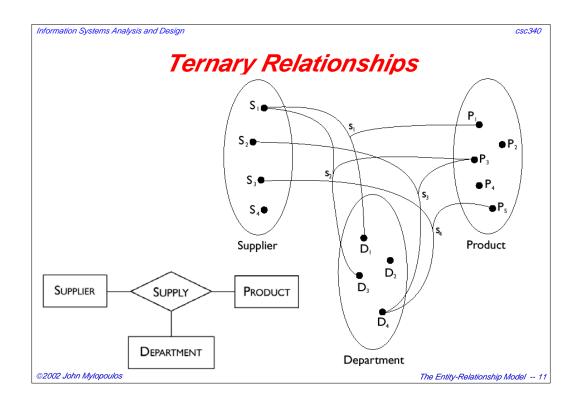

Information Systems Analysis and Design

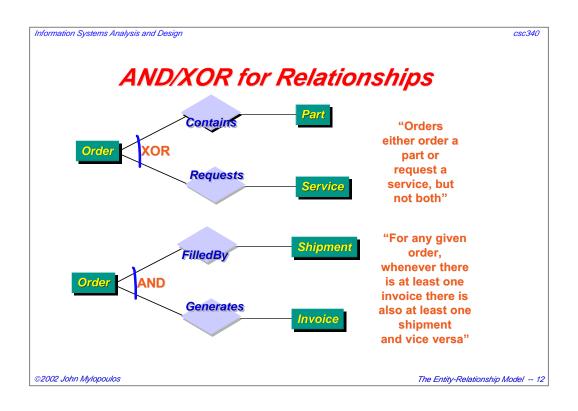

Note in the second example that the relationship is not symmetric. In this case it is necessary to indicate the two roles that the entity involved plays in the relationship.

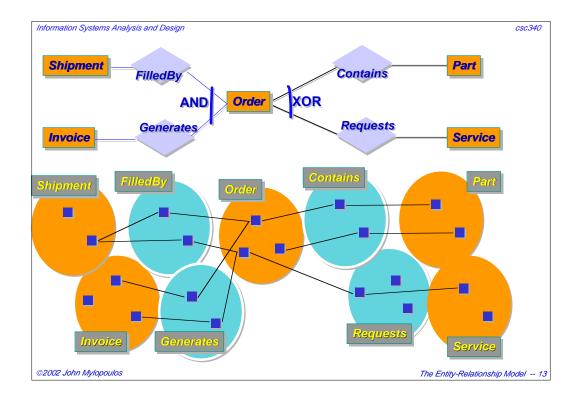

©2002 John Mylopoulos

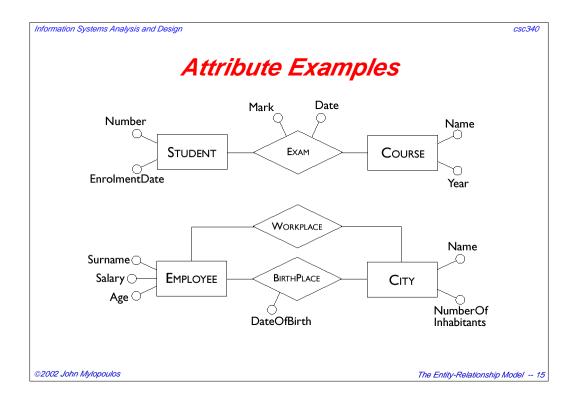

csc340

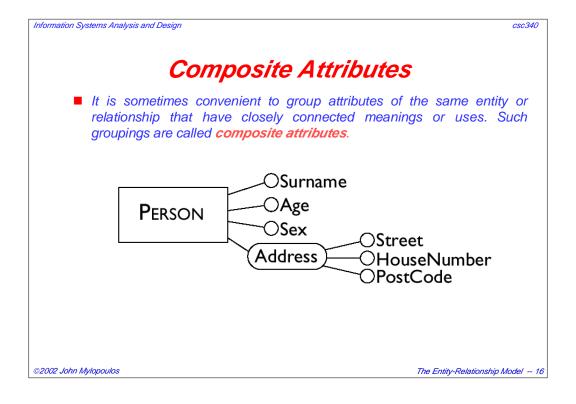

Attributes

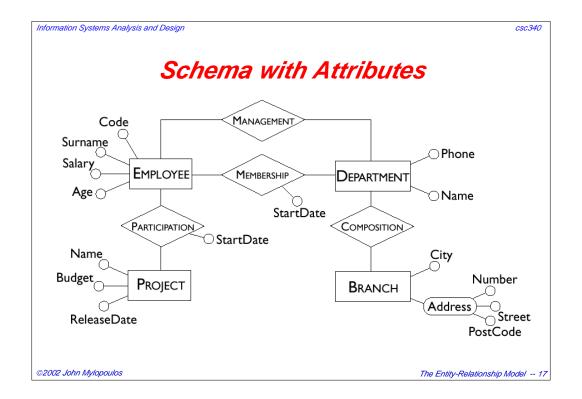

- These describe the elementary properties of entities or relationships.
- For example, Surname, Salary and Age are possible attributes of the Employee entity, while Date and Mark are possible attributes for the relationship Exam between Student and Course.
- An attribute associates with each instance of an entity (or relationship) a value belonging to a set known as the **domain** of the attribute.
- The domain contains the admissible values for the attribute.

©2002 John Mylopoulos

csc340

Cardinalities

- These are specified for each entity participating in a relationship and describe the maximum and minimum number of relationship occurrences in which an entity occurrence can participate.
- Cardinalities state how many times can an entity instance participate in instances of a given relationship.

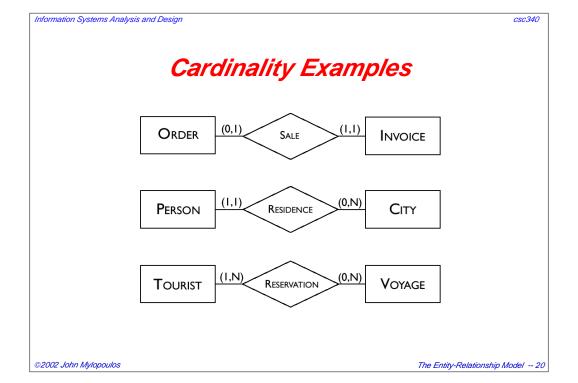

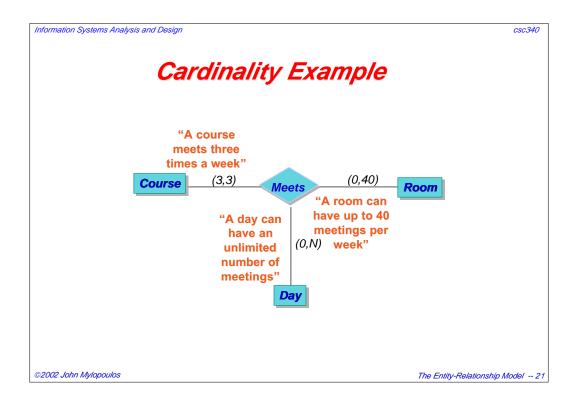

©2002 John Mylopoulos

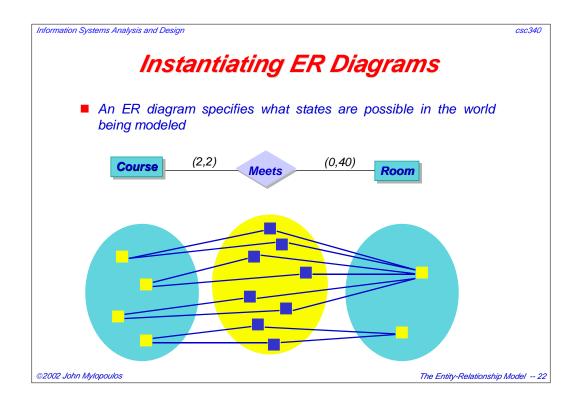

Cardinalities (cont'd)

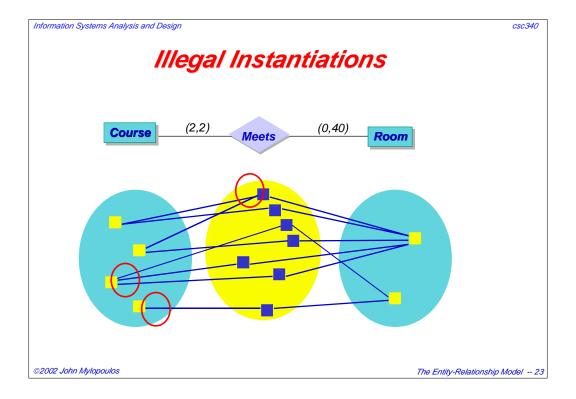

- In principle, a cardinality is any pair of non-negative integers (n,m) such that n≤m. or a pair of the form (n,N) where N means "any number".
- If minimum cardinality is 0, we say that entity participation in a relationship is optional. If minimum cardinality is 1, we say that entity participation in a relationship is mandatory.
- If maximum cardinality is 1, each instance of the entity is associated at most with a single instance of the relationship; if maximum cardinality is N, then each instance of the entity is associated with an arbitrary number of instances of the relationship.

©2002 John Mylopoulos

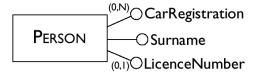

csc340

Cardinalities of Attributes

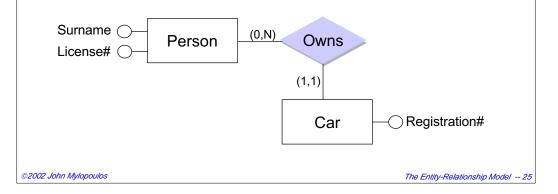

- They are specified for the attributes of entities (or relationships) and describe the minimum and maximum number of values of the attribute associated with instances of an entity or a relationship.
- In most cases, the cardinality of an attribute is equal to (1,1) and is omitted (single-valued attributes)
- The value of a certain attribute however, may also be null, or there
 may exist several values of a certain attribute for an entity instance
 (multi-valued attributes)

©2002 John Mylopoulos

Cardinalities (cont'd)

Multi-valued attributes should be used with great caution, because they represent situations that can be modelled in many cases with additional entities linked by one-to-many (or many-to-many) relationships to the entity to which they refer.

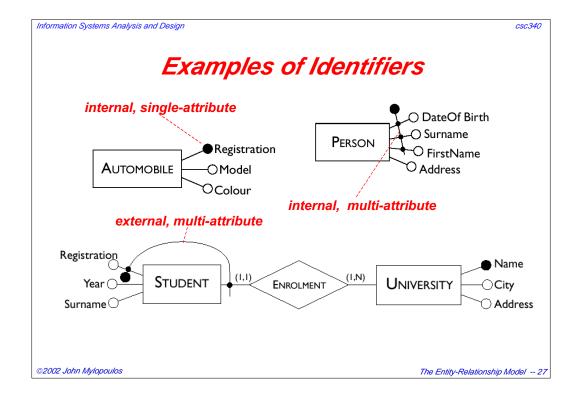

Information Systems Analysis and Design

csc340

Identifiers

- Identifiers (or keys) consist of one or more attributes which identify uniquely instances of an entity.
- In many cases, an identifier is formed by one or more attributes of the entity itself: in this case we talk about an *internal* identifier.
- Sometimes, however, the attributes of an entity are not sufficient to identify its instances unambiguously and other entities are involved in the identification. Identifiers of this type are called external identifiers.
- An identifier for a relationship consists of identifiers for all the entities it relates. For example, the identifier for the relationship (Person-) Owns(-Car) is a combination of the Person and Car identifiers.

©2002 John Mylopoulos

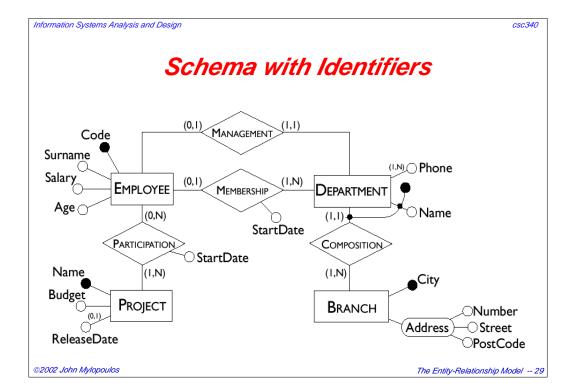

csc340

General Observations on Identifiers

- An identifier can involve one or more attributes, provided that each of them has (1,1) cardinality;
- An external identifier can involve one or more entities, provided that each of them is member of a relationship to which the entity to identify participates with cardinality equal to (1,1);
- An external identifier can involve an entity that is in its turn identified externally, as long as cycles are not generated;
- Each entity must have one (internal or external) identifier, but can have more than one. Actually, if there is more than one identifier, then the attributes and entities involved in an identification can be optional (minimum cardinality equal to 0).

©2002 John Mylopoulos

csc340

Modeling an Application with Identifiers

Identifiers constitute a powerful mechanism for modeling an application.

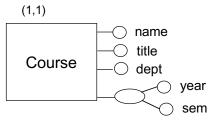

Assume we want a database storing information about lecture meetings.

- Suppose first that we use the identifier coursename, day, hour for the Meeting entity. This says, that there can only be one meeting at any one time for a given course name, day, hour; in other words, we can't have two sections of the same course meeting at the same day+hour.
- Suppose now we use only coursename as identifier for Meeting. This says that there can only be one meeting per given course name (unreasonable!)
- If we use courseinstructor, room as identifier for Meeting, we are stating that there can only be one meeting for a given instructor+room combination, so an instructor must have all her meetings in different rooms!
- Finally, if the attribute courseinstructor by itself forms an identifier for Meeting, then the diagram we have built is stating that each instructor participates in at most one meeting, again this is unreasonable.

©2002 John Mylopoulos

Consider...

- Assume that we want to keep track of course offerings over the years.
- ■What does each of the following combinations of attributes say about the application?
 - √ name;

Information Systems Analysis and Design

- ✓ name, sem, year;
- ✓ sem, year;
- ✓ name, dept;
- ✓ dept, year.

©2002 John Mylopoulos

The Entity-Relationship Model -- 31

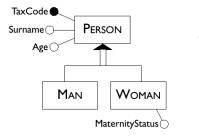

Information Systems Analysis and Design

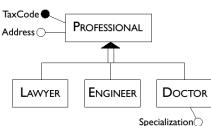

csc340

csc340

Generalizations

- These represent logical links between an entity E, known as *parent* entity, and one or more entities E₁,...,E_n called *child* entities, of which E is more general, in the sense that they are a particular case.
- In this situation we say that E is a **generalization** of $E_1,...,E_n$ and that the entities $E_1,...,E_n$ are **specializations** of E.

©2002 John Mylopoulos

Properties of Generalization

- Every instance of a child entity is also an instance of the parent entity.
- Every property of the parent entity (attribute, identifier, relationship or other generalization) is also a property of a child entity. This property of generalizations is known as inheritance.

©2002 John Mylopoulos

The Entity-Relationship Model -- 33

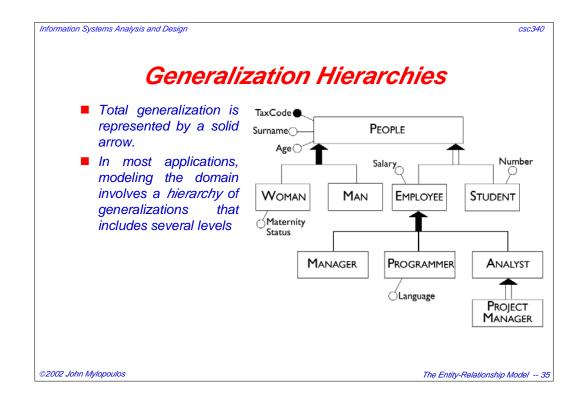

Information Systems Analysis and Design

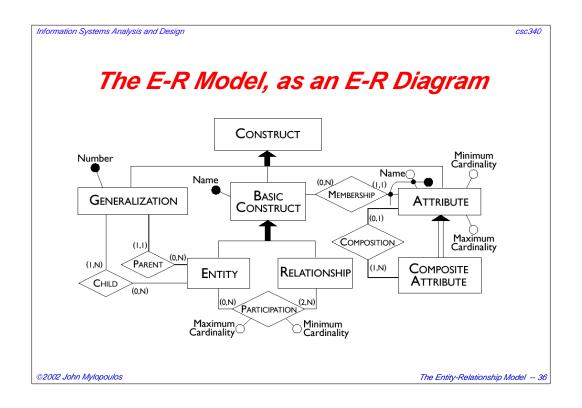

csc340

Types of Generalizations

- A generalization is *total* if every instance of the parent entity is also an instance of one of its children, otherwise it is *partial*.
- A generalization is exclusive if every instance of the parent entity is at most an instance of one of the children, otherwise it is overlapping.
- The generalization Person, of Man and Woman is total (the sets of men and the women constitute 'all' the people) and exclusive (a person is either a man or a woman).
- The generalization Vehicle of Automobile and Bicycle is partial and exclusive, because there are other types of vehicle (for example, motor bike) that are neither cars nor bicycle.
- The generalization Person of Student and Employee is partial and overlapping, because there are students who are also employed.

Example

We wish to create a database for a company that runs training courses. For this, we must store data about the trainees and the instructors. For each course participant (about 5,000), identified by a code, we want to store her social security number, surname, age, sex, place of birth, employer's name, address and telephone number, previous employers (and periods employed), the courses attended (there are about 200 courses) and the final assessment for each course. We need also to represent the seminars that each participant is attending at present and, for each day, the places and times the classes are held.

Each course has a code and a title and any course can be given any number of times. Each time a particular course is given, we will call it an 'edition' of the course. For each edition, we represent the start date, the end date, and the number of participants. If a trainee is self-employed, we need to know her area of expertise, and, if appropriate, her title. For somebody who works for a company, we store the level and position held. For each instructor (about 300), we will show the surname, age, place of birth, the edition of the course taught, those taught in the past and the courses that the tutor is qualified to teach. All the instructors' telephone numbers are also stored. An instructor can be permanently employed by the training company or freelance.

Glossary Example

Term	Description	Synonym	Links
Trainee	Participant in a course. Can be an employee or self-employed.	Participant	Course, Company
Instructor	Course tutor. Can be freelance.	Tutor	Course
Course	Course offered. Can have various editions.	Seminar	Instructor, Trainee
Company	Company by which a trainee is employed or has been employed.		Trainee

Structuring of Requirements (I)

Phrases of a general nature

We wish to create a database for a company that runs training courses. We wish to maintain data for the trainees and the instructors.

Phrases relating to trainees

For each trainee (about 5000), identified by a code, the database will hold the social security number, surname, age, sex, town of birth, current employer, previous employers (along with the start date and the end date of the period employed), the editions of the courses the trainee is attending at present and those he or she has attended in the past, with the final marks out of ten.

Phrases relating to the employers of trainees

For each employer of a trainee the database will store name, address and telephone number.

©2002 John Mylopoulos

Structuring of Requirements (II)

Phrases relating to courses

For each course (about 200), we will hold the name and code. Each time a particular course is given, we will call it an 'edition' of the course. For each edition, we will hold the start date, the end date, and the number of participants. For the editions currently in progress, we will hold the dates, the classrooms and the times in which the classes are held.

Phrases relating to specific types of trainee

For a trainee who is a self-employed professional, we will hold the area of expertise and, if appropriate, the professional title. For a trainee who is an employee, we will hold the level and position held.

Phrases relating to instructors

For each instructor (about 300), we will hold surname, age, town of birth, all telephone numbers, the edition of courses taught, those taught in the past and the courses the instructor is qualified to teach. The instructors can be permanently employed by the training company or can be freelance.

The Entity-Relationship Model -- 43

Information Systems Analysis and Design

csc340

Operational Requirements

- operation 1: insert a new trainee including all her data (to be carried out approximately 40 times a day);
- **operation 2**: assign a trainee to an edition of a course (50 times a day);
- operation 3: insert a new instructor, including all his or her data and the courses he or she is qualified to teach (twice a day);
- operation 4: assign a qualified instructor to an edition of a course (15 times a day);
- operation 5: display all the information on the past editions of a course with title, class timetables and number of trainees (10 times a day);
- operation 6: display all the courses offered, with information on the instructors who are qualified to teach them (20 times a day);
- operation 7: for each instructor, find the trainees for all the courses he or she is teaching or has taught (5 times a week);
- operation 8: carry out a statistical analysis of all the trainees with all the information about them, about the editions of courses they have attended and the marks obtained (10 times a month).

Conceptual Design with the ER Model

Design choices:

- Should a concept be modeled as an entity or an attribute?
- Should a concept be modeled as an entity or a relationship?
- Identifying relationships: Binary or ternary? Aggregation? Constraints on the ER Model:
- A lot of data semantics can (and should) be captured.
- But some constraints cannot be captured by ER diagrams.

©2002 John Mylopoulos

The Entity-Relationship Model -- 45

Information Systems Analysis and Design

csc340

Some Rules of Thumb

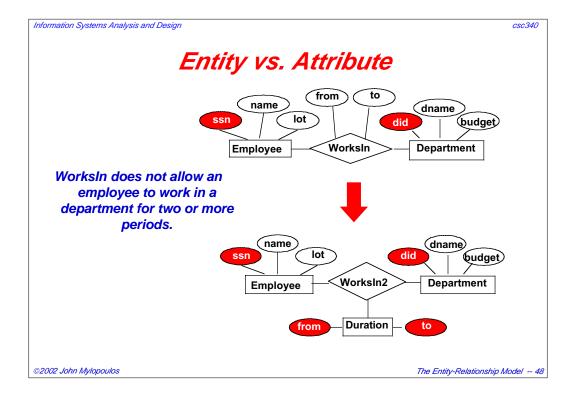

- If a concept has significant properties and/or describes classes of objects with an autonomous existence, it is appropriate to represent it as an entity.
- If a concept has a simple structure, and has no relevant properties associated with it, it is convenient to represent it with an attribute of another concept to which it refers.
- If a concept provides a logical link between two (or more) entities, it is convenient to represent it with a relationship.
- If one or more concepts are particular cases of another concept, it is convenient to represent them in terms of a generalization relationship.

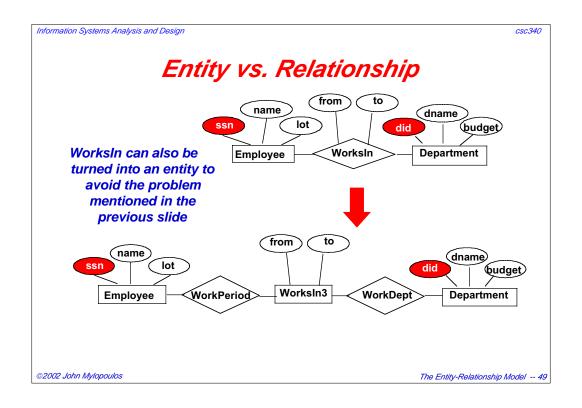

©2002 John Mylopoulos

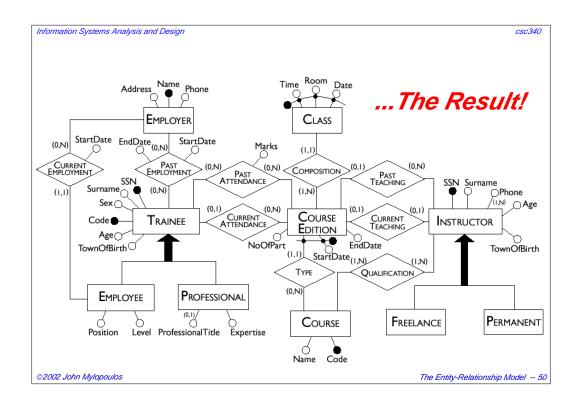

Examples

- Consider **address** of a trainee. Is it an entity or relationship?
- Consider address for a telephone company database, which has to keep track of how many and what type of phones are available in any one household, who lives there (there may be several phone bills going to the same address) etc.
- How do we represent employment of a trainee by a particular employer?
- How do we represent a course edition?

©2002 John Mylopoulos

Documentation of an E-R Schema

- An Entity-Relationship schema is rarely sufficient by itself to represent all the aspects of an application in detail.
- It is therefore important to complement every E-R schema with support documentation, which can facilitate the interpretation of the schema itself and describe properties of the data that cannot be expressed directly by the constructs of the model.
- A widely-used documentation concept for conceptual schemas is the **business rule**.

©2002 John Mylopoulos

The Entity-Relationship Model -- 51

Information Systems Analysis and Design

csc340

Business Rules

- Business rules are used to describe the properties of an application, e.g., the fact that an employee cannot earn more than his or her manager.
- A business rule can be:
 - ✓ the description of a concept relevant to the application (also known as a business object),
 - ✓ an integrity constraint on the data of the application,
 - ✓ a derivation rule, whereby information can be derived from other information within a schema.

©2002 John Mylopoulos

Documentation Techniques

- Descriptive business rules can be organized as a data dictionary. This is made up of two tables: the first describes the entities of the schema, the others describes the relationships.
- Business rules that describe constraints can be expressed in the following form:

<concept> must/must not <expression on concepts>

Business rules that describe derivations can be expressed in the following form:

<concept> is obtained by <operations on concepts>

©2002 John Mylopoulos

The Entity-Relationship Model -- 53

Information Systems Analysis and Design

csc340

Example of a Data Dictionary

Entity	Description	Attributes	Identifier
EMPLOYEE	Employee working in the company.	Code, Surname, Salary, Age	Code
PROJECT	Company project on which employees are working.	Name, Budget, ReleaseDate	Name

Relationship	Description	Entities involved	Attributes
MANAGEMENT	Associate a manager with a department.	Employee (0,1), Department (1,1)	
MEMBERSHIP	Associate an employee with a department.	Employee (0,1) Department (1,N)	StartDate

©2002 John Mylopoulos

Examples of Business Rules

Constraints

(BR1) The manager of a department must belong to that department.

(BR2) An employee must not have a salary greater than that of the manager of the department to which he or she belongs.

(BR3) A department of the Rome branch must be managed by an employee with more than 10 years' employment with the company.

(BR4) An employee who does not belong to a particular department must not participate in any project.

....

Derivations

(BR5) The budget for a project is obtained by multiplying the sum of the salaries of the employees who are working on it by 3.

....

The Entity-Relationship Model -- 55

Information Systems Analysis and Design

000340

Comparison of ER and Class Diagrams

- ER diagrams allow N-ary relationships, N≥2; Class diagrams only allow binary relationships.
- ER diagrams allow multi-valued attributes, class diagrams do not.
- ER diagrams allow the specification of identifiers (an often-encountered type of constraint), while class diagrams do not.
- Class diagrams allow dynamic classification, but ER diagrams do not.

©2002 John Mylopoulos
