Databases

A database is a collection of persistent data shared by a number of applications.

Databases have been founded on the concept of data Independence Applications should not have to know the organization of the data or the access strategy employed

Need query processing facility, which generates automatically an access plan, given a query

Databases also founded on the concept of data sharing: Applications should be able to work on the same data concurrently, without knowing of each others' existence.

Database procedures defined in terms of atomic operations called transactions

Conventional Files vs Databases

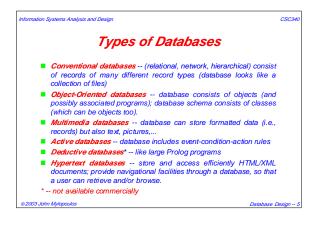

Conventional Files vs Databases

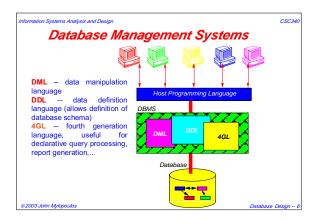

Databases

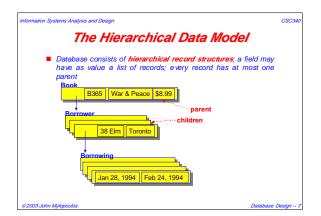

Advantages — Good for data integration; allow for more flexible formats (not just records)
good for simple applications; very efficient

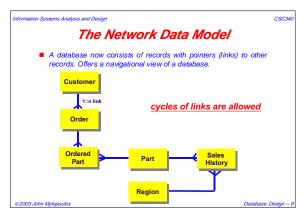

Disadvantages — data duplication; hard to evolve; hard to build for complex applications

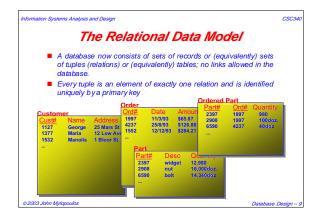

The future is with databases!

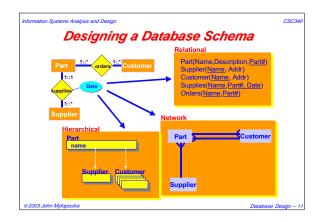

Comparing Data Models

The oldest DBMSs were hierarchical, dating back to the mid-60s. IMS (IBM product) is the most popular among them. Many old databases are hierarchical.

The network data model came next (early '70s). At the time of its proposal, it was viewed as a breakthrough. It emphasized the role of the database programmer as "navigator", chasing links (pointers, actually) around a database.

But, the network model was found to be in many respects too implementation-oriented, not insulating sufficiently the programmer from implementation features of network DBMSs.

The relational model is the most recent arrival (early '80s) and it has taken over the database market. Relational databases are considered simpler than their hierarchical and network cousins because they don't allow any links/pointers (which are necessarily implementation-dependent).

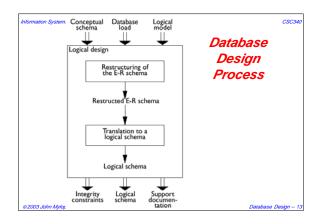

| The aim of database design is to construct a relational schema that correctly and efficiently represents all of the information described by a class or Entity-Relationship diagram (or 'schema') produced during requirements analysis.
| From now, we'll only talk about transforming an E-R schema into a relational schema. Most of the transformation process applies for class diagrams as well.
| This is not just a simple translation from one model to another for two main reasons:

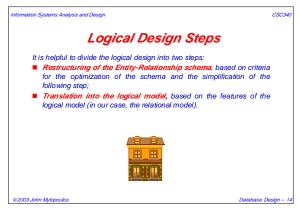

✓ not all the constructs of the Entity-Relationship model can be translated naturally into the relational model;

✓ the schema must be restructured in such a way as to make the execution of the projected operations as efficient as possible.

tion Systems Analysis and Design

Performance Analysis

An ER schema can be restructured to optimize two parameters:

'Cost of an operation (evaluated in terms of the number of occurrences of entities and relationships that are visited during the execution of an operation on the database);

'Storage requirements (evaluated in terms of number of bytes necessary to store the data described by the schema).

In order to study these parameters, we need to know.

'Projected volume of data;

'Projected operation characteristics.

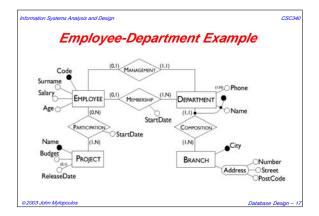

Cost Model

The cost of an operation is measured in terms of the number of disk accesses required. A disk access is, generally orders of magnitude more expensive than in-memory accesses, or CPU operations.

For a coarse estimate of cost, we will assume that

a Read operation (for one tuple) requires 1 disk access

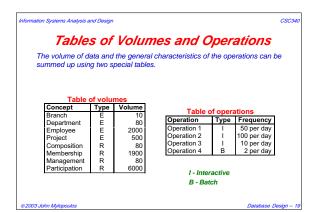

A Write operation (for one tuple) requires 2 disk accesses (read from disk, change, write back to disk)

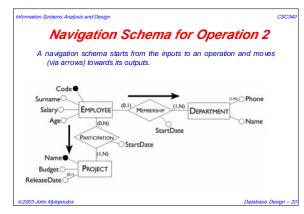

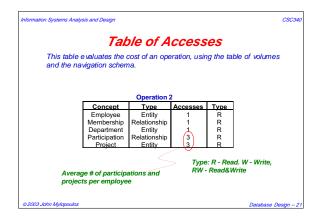

Typical Operations

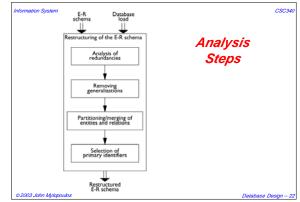

Operation 1: Assign an employee to a project.
Operation 2: Find the record of an employee, including the department where she works, and the projects she works for.
Operation 3: Find the records of all employees for a given department.
Operation 4: For each branch, retrieve its departments, and for each department, retrieve the last names of their managers, and the list of their employees.

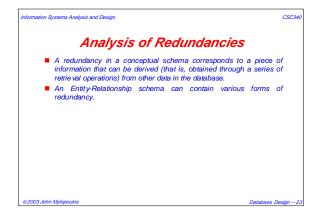

Note: For class diagrams, these would be operations associated with database classes.

ion Systems Analysis and Desig CSC34 Access Tables The attribute NumberOfParticipants in CourseEdition can be derived from the relationships CurrentAttendance and PastAttendance. Operation 2 without redundancy Concept Type Acc Type Concept Type Acc Type Trainee urrentAtt'nce R W CourseEdition ourseEdition Concept CourseEdition Type Acc Type Type Acc Type Concept Type Course RERE 5 Type Course Composition R R R Composition Class 40 40 PastAtt'nce Class

Analysis of Redundancy

From the access tables we obtain (giving double weight to the write accesse):

- accesses):

 ✓ presence of redundancy for operation 2 we have 100 read disk accesses and 200 write disk accesses per day, for operation 5 we
 - accesses and 200 write disk accesses per day, for operation 5 we have 910 read accesses per day, for a total of 1,210 disk accesses per day,
- without redundancy: for operation 2 we have 50 read accesses per day and 100 write accesses per day, for operation 5, we have 1,410 read accesses per day, for a total of 1,560 accesses per day.
- Thus, redundancy makes sense in this case, so we leave NumberOfParticipants as an attribute of the entity CourseEdition.

nformation Systems Analysis and Design

Removing Generalizations

- For the generalization on instructors:
 - the relevant operations make no distinction between the child entities and these entities have no specific attributes:
 - we can therefore delete the child entities and add an attribute Type to the parent entity.
- For the generalization on trainees:
- the relevant operations make no distinction between the child entities, but these entities have specific attributes;
- we can therefore leave all the entities and add two relationships to link each child with the parent entity: in this way, we will have no attributes with possible null values on the parent entity and the dimension of the relations will be reduced.

maior dystand margin and Dough

Partitioning and Merging of Concepts

- The relationships PastTeaching and PresentTeaching can be merged since they describe similar concepts between which the operations make no difference. A similar consideration applies to the relationships PastAttendance and PresentAttendance.
- The multi-valued attribute Telephone can be removed from the Instructor entity by introducing a new entity Telephone linked by a one-to-many relationship to the Instructor entity.

Information Systems Analysis and Design

CSC340

✓ there are two identifiers: the social security number and the internal code;

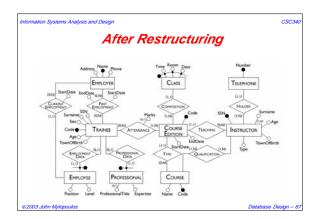

Choice of Main Identifiers

- it is far preferable to choose the latter: a social security number will require several bytes whereas an internal code, which serves to distinguish between 5000 occurrences, requires a few bytes.
- CourseEdition entity:
 - ✓ it is identified externally by the StartDate attribute and by the Course entity;
 - we can see however that we can easily generate for each edition a code from the course code: this code is simpler and can replace the external identifier.

Database Design -- t

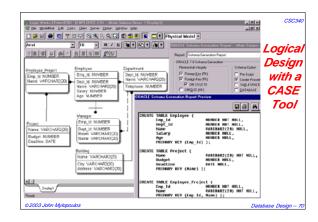

Logical Design Using CASE Tools

The logical design phase is partially supported by database design tools:

the translation to the relational model is carried out by such tools semi-automatically;
the restructuring step is difficult to automate and CASE tools provide little or no support for it.

Most commercial CASE tools will generate automatically SQL code for the creation of the database.

Some tools allow direct connection with a DBMS and can construct the corresponding database automatically.

ation Systems Analysis and Design What is a Good Relational Schema Like? ■ Some relational schemas are "better" representations than others. What are the criteria we can use to decide whether a diagram is better than another? Should we have more/fewer relations as opposed to attributes? Enter normal forms An attribute a functionally) depends on a set of attributes a₁, a₂, ..., a_n if these determine uniquely the value of a for every tuple of the relation where the vappear together $a_1, a_2, ..., a_n --> a$ ■ Example: For the relation Course(name,title,instrName,rmName,address), E.g. (csc340, "Analysis and Design", JM, WB116, "48 College") the title attribute depends on the name attribute. Likewise, the address attribute depends on the rmName attribute, name --> title , also rmName --> address 2003 John Mylopoulos Database Design -- 71

Examples of Functional Dependencies

Examples of Functional Dependencies

CSC340

CSC340

Examples of Functional Dependencies

CSC340

CSC340

CSC340

Examples of Functional Dependencies

Supplier (S\frac{\frac{1}{2}}{2}, SName, Status, Address)

Here SName, Status, Address functionally depend on S\frac{1}{2} because S\frac{1}{2} uniquely determines the values of the other attributes of the Supplier relation

S\frac{1}{2} -> SName, Status, Address

Likewise, assuming that Lastname, Firstname uniquely identify people, we have

Lastname, Firstname --> Salary, Address

In general, for any relation, non-key attributes should functionally depend on key ones.

Information Systems Analysis and Design

CSC340

What's Wrong with Un-Normalized Relations?

- Normalization helps produce a schema that is not redundant and does not suffer from anomalies.
- Consider Emp(Emp#, Ename, Address, Dept, Mngr#)

 with Empl# --> EName, Address, Dept, Mngr#,

 Dept --> Mngr#
- Insertion anomaly: We can't add information about a new department and its manager until we have an employee in that department.
- Deletion anomaly: If we delete the only employee in a department, we lose information about the department (e.g., its manager)
- Update anomaly: If we update the Mngr# attribute of one tuple, we must do it for all, otherwise we have an inconsistent database.

It's easy to end up with an inconsistent database when it's not normalized!

CSC340

Normalizing Relational Schemas: 1NF

 A relation is in First Normal Form (1NF) if it does not include any multivalued attributes or any composite attributes. Multi-valued attributes e.g., consider the relation

Course(name, title, instrName*, studentNo*, addr)

Course is not in 1NF because of two attribute groups that repeat
(instructor and student groups)

To place a relation in 1NF, take each multi-valued attribute or composite attribute and promote it into an relation in its own right.

Database Design -- 75

Information Systems Analysis and Design

.....

An Example

■ For the Course(<u>name</u>,title,instrName*,studentNo*,addr), example, assume that addr is a composite attribute consisting of a streetNm, streetNo,city and postalCode:

==> Course(name, title)

CourseStudt(name, studentNo)
CourseInstr(name, instName)

CourseAddr(<u>name</u>,streetNm,streetNo,city,postalCode)

 The process outlined earlier does ensure that there are no multivalued attributes for the relational schema generated from a conceptual schema

CSC340

Normalizing Relational Schemas: 2NF

- An relation is in Second Normal Form (2NF) if it is in 1NF and, moreover, all non-key attributes depend on all elements of its key, rather than a subset.
- v Consider
- Room(street,number,bldgNm,room#,capacity,AVEquip)
- Room is not in 2NF because its address attributes functionally depend on its bldgNm key element, rather than the combination (room#, bldgNm)
- To place a 1NF relation into 2NF, take each non-key attribute that does not depend on the full key and move it to a relation identified by the partial key
 - >> Room(bldgNm,room#,capacity,AVEquip),
 Building(bldgNm,street,number)

© 2003 John Mylopoulos

Natahasa Nasinn ... 77

Normalizing Relational Schemas: 3NF

- A relation is in Third Normal Form (3NF) if it is in 2NF and none of its non-key attributes depends on any other non-key attribute.
- Assuming that each course has only one instructor (why do we need this assumption?). Course is not in 3NF because instribept.
 - depends on instrNm:
 Course(name, year, sem, instrNm, instrDept, enrol#)
- To place a 2NF relation into 3NF, move each non-key attribute that depends on other non-key attributes to another relation
