The Entity-Relationship Model -- 1

Information Systems Analysis and Design

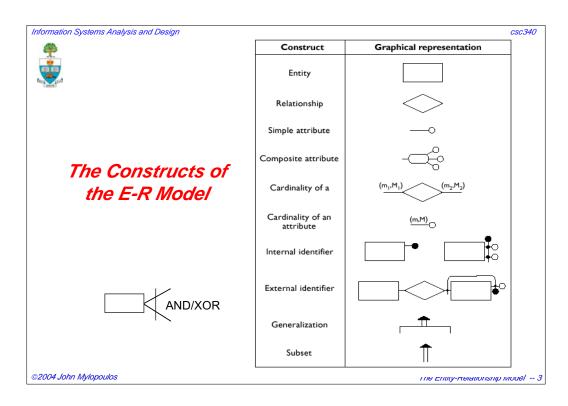

# The Entity Relationship Model

- The *Entity-Relationship* (ER) *model* is a *conceptual* data model, capable of describing the data requirements for a new information system in a direct and easy to understand graphical notation.
- Data requirements are described in terms of a conceptual (or, ER) schema.
- ER schemata are comparable to class diagrams.

©2004 John Mylopoulos

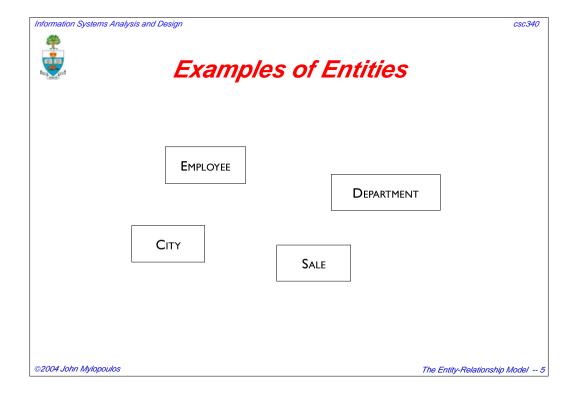

csc340

### **Entities**

- Represent classes of objects (facts, things, people,...) that have properties in common and an autonomous existence, e.g., City, Department, Employee, Purchase and Sale.
- An instance of an entity is an object in the class represented by the entity, e.g., Stockholm, Helsinki, are examples of instances of the entity City; Peterson and Johanson are examples of instances of the Employee entity.
- [The E-R model is very different from the relational model in which it is not possible to represent an object without knowing its properties, e.g., an employee is represented by a tuple containing the name, surname, age, and other attributes.]

©2004 John Mylopoulos

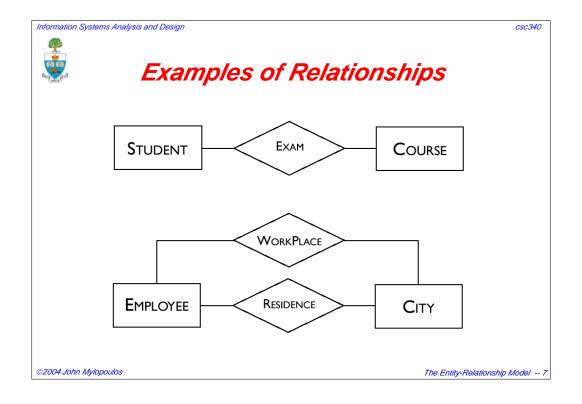

csc340

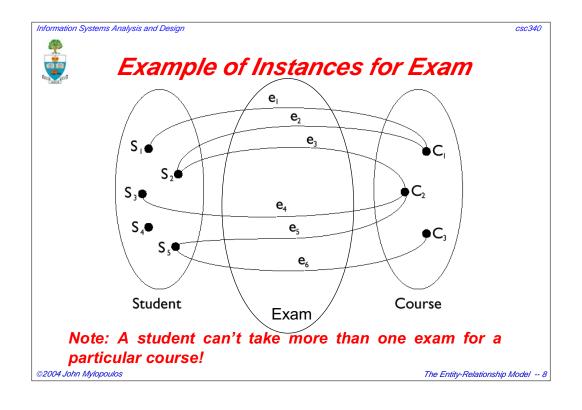

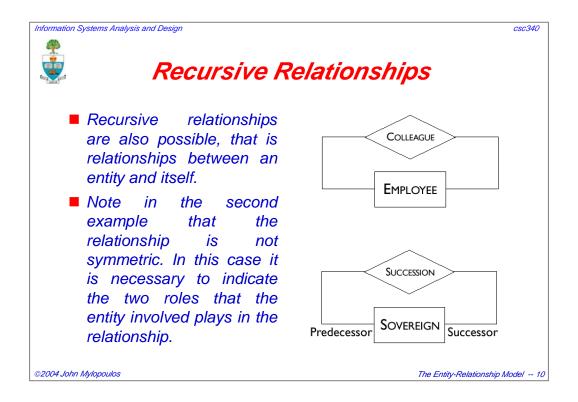

# Relationships

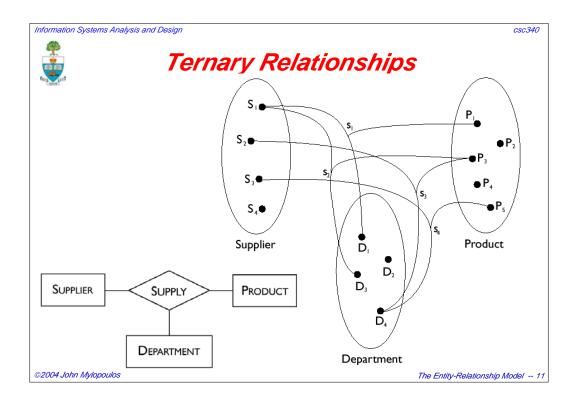

- They represent associations between two or more entities.
- Residence is an example of a relationship that can exist between the entities City and Employee; Exam is an example of a relationship that can exist between the entities Student and Course.
- An instance of a relationship is an n-tuple made up of instances of entities, one for each of the entities involved.
- The pair (Johanssen,Stockholm), or the pair (Peterson,Oslo), are examples of instances of the relationship Residence.
- Note: The collection of instances of a relationship is by definition a set, not a bag; i.e., no duplicates!

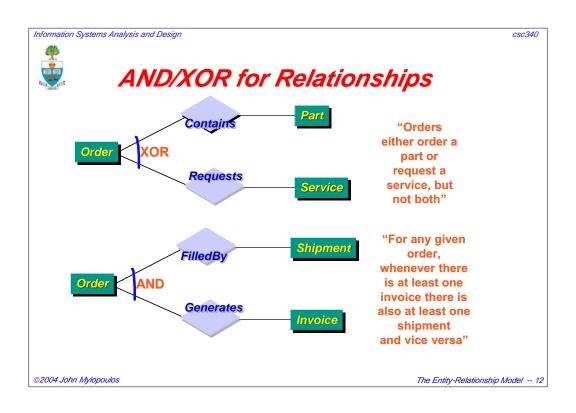

©2004 John Mylopoulos

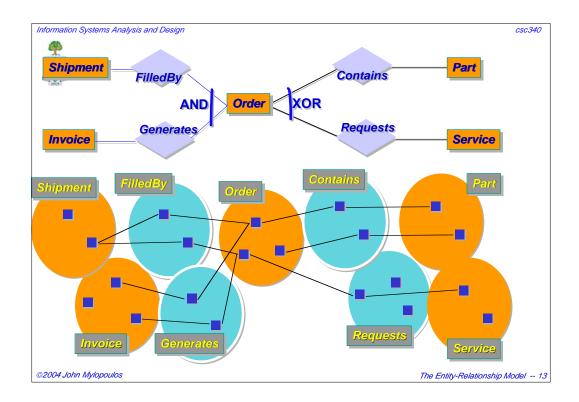

csc340

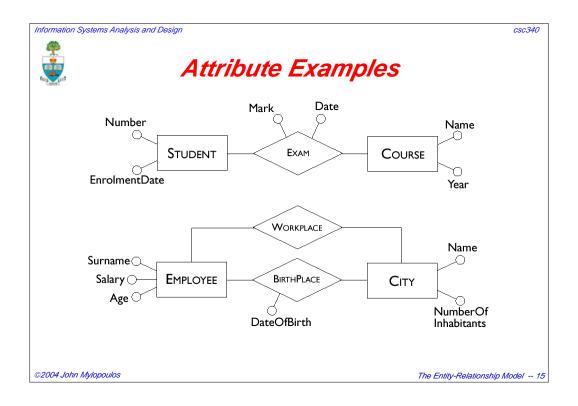

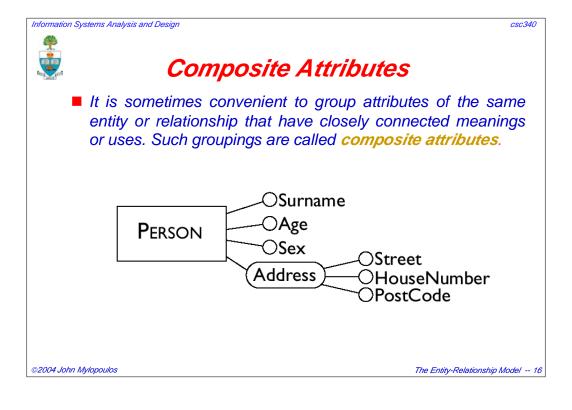

# **Attributes**

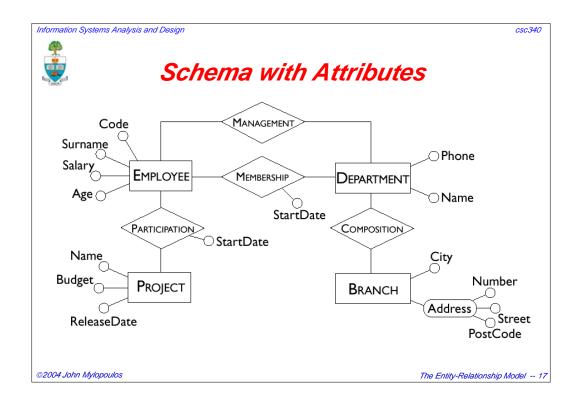

- Describe elementary properties of entities or relationships.
- For example, Surname, Salary and Age are attributes of Employee, while Date and Mark are attributes of relationship Exam between Student and Course.
- An attribute associates with each instance of an entity (or relationship) one or more values belonging to its domain.
- Attributes may be single-valued, or multi-valued.

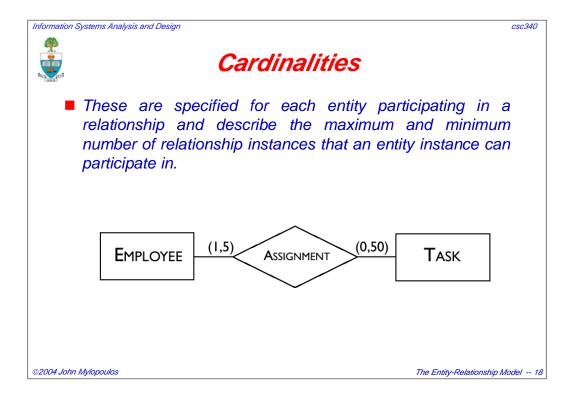

©2004 John Mylopoulos

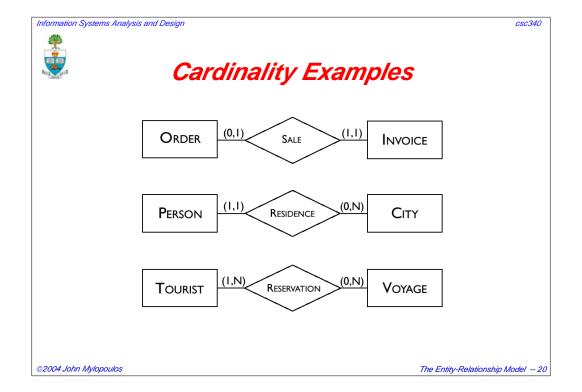

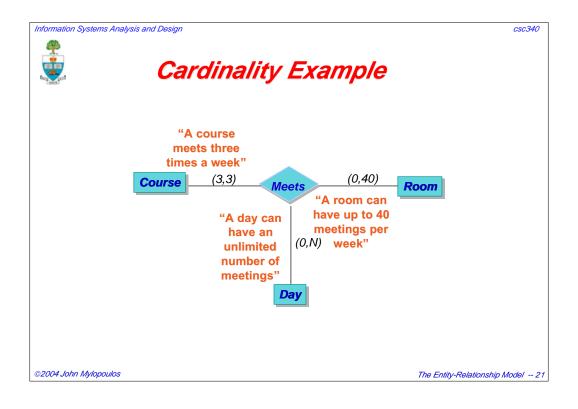

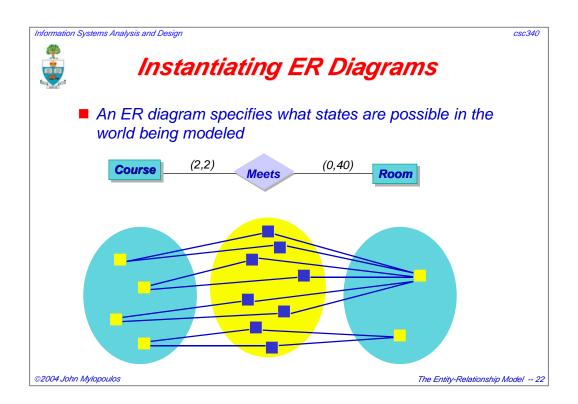

# Cardinalities (cont'd)

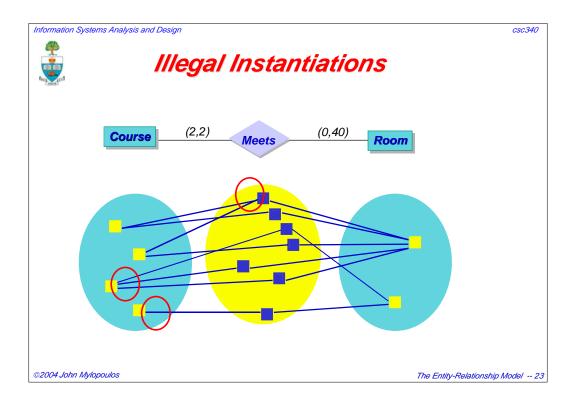

- In principle, a cardinality is any pair of non-negative integers (n,m) such that n≤m. or a pair of the form (n,N) where N means "any number".
- If minimum cardinality is 0, entity participation in a relationship is optional. If minimum cardinality is 1, entity participation in a relationship is mandatory.
- If maximum cardinality is 1, each instance of the entity is associated at most with a single instance of the relationship; if maximum cardinality is N, then each instance of the entity is associated with an arbitrary number of instances of the relationship.

©2004 John Mylopoulos

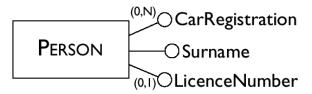

csc340

# **Cardinalities of Attributes**

- Describe the minimum and maximum number of values an attribute can have.
- In most cases, the cardinality of an attribute is (1,1) and is omitted (single-valued attributes)
- The value of an attribute, however, may also be null, or there may be several values (*multi-valued* attributes)

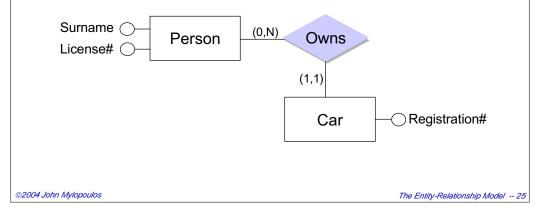

©2004 John Mylopoulos

# Cardinalities (cont'd)

- Multi-valued attributes often represent situations that can be modelled with additional entities.
- For example, the ER diagram of the previous slide can be revised into:

Information Systems Analysis and Design

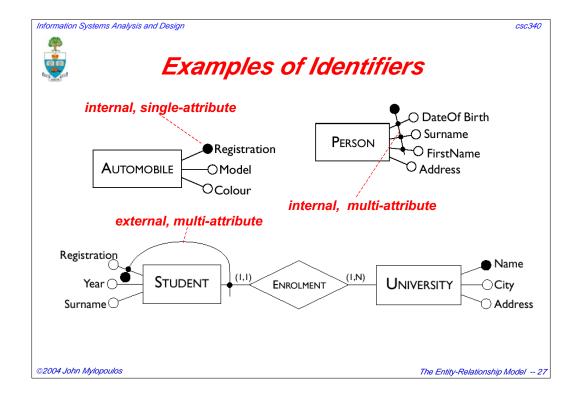

csc340

### **Identifiers**

- *Identifiers* (or *keys*) consist of one or more attributes which identify uniquely instances of an entity.
- For example, Person may be identified by the attribute socialInsurance#. Alternatively, it may be identified by firstName, middleName, lastName, address.
- In most cases, an identifier is formed by one or more attributes of the entity itself (internal identifier).
- Sometimes, the attributes of an entity are not sufficient to identify its instances and other entities are involved in the identification (external identifiers).
- An identifier for a relationship consists of identifiers for all the entities it relates.

©2004 John Mylopoulos

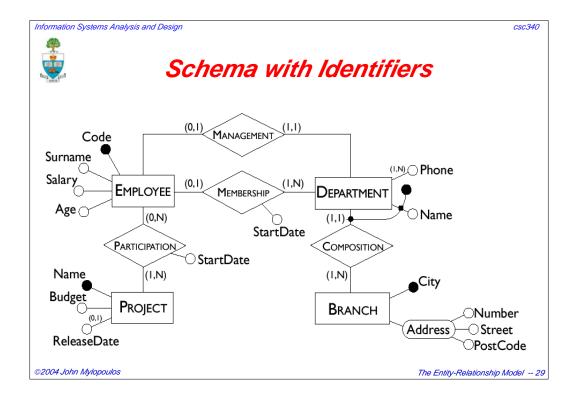

csc340

### General Observations on Identifiers

- An identifier may consist of one or more attributes, provided that each of them has (1,1) cardinality.
- An external identifier can involve one or more entities, provided that each of them is member of a relationship to which the entity to identify participates with cardinality equal to (1,1).
- An external identifier may involve an entity that is itself identified externally, as long as cycles are not generated.
- Each entity must have at least one (internal or external) identifier. If there is more than one identifier, then the attributes and entities involved in an identification can be optional (minimum cardinality equal to 0).

cec 340

# **Modeling an Application with Identifiers**

Identifiers constitute a powerful mechanism for modeling an application. Assume we want a database storing information about lecture meetings.

- Suppose first that we use the identifier coursename, day, hour for the Meeting entity. This says, that there can only be one meeting at any one time for a given course name, day, hour; in other words, we can't have two sections of the same course meeting at the same day+hour.
- Suppose now we use only coursename as identifier for Meeting. This says that there can only be one meeting per given course name (unreasonable!)

©2004 John Mylopoulos

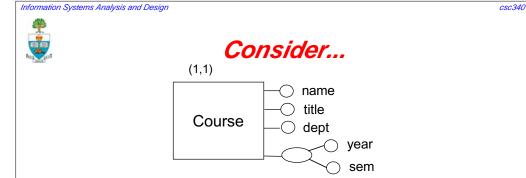

# More Examples

- If we use courseinstructor, room as identifier for Meeting, we are stating that there can only be one meeting for a given instructor+room combination, so an instructor must have all her meetings in different rooms!
- Finally, if the attribute courseinstructor by itself forms an identifier for Meeting, then the diagram we have built is stating that each instructor participates in at most one meeting, again this is unreasonable.

©2004 John Mylopoulos

The Entity-Relationship Model -- 31

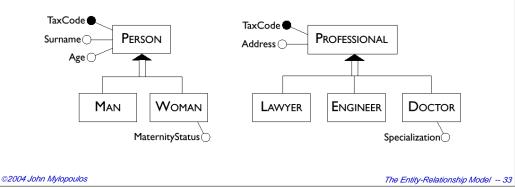

- Suppose we want information on course offerings over the years. What does each of the following identifiers say about the application?
  - ✓ name:
  - ✓ name, sem, year;
  - ✓ sem, year;
  - ✓ name, dept;
  - ✓ dept, year.

©2004 John Mylopoulos

### **Generalizations**

- Represent logical links between an entity E, known as *parent* entity, and one or more entities E<sub>1</sub>,...,E<sub>n</sub> called *child* entities, of which E is more general.
- We then say that E is a **generalization** of  $E_1,...,E_n$  and that the entities  $E_1,...,E_n$  are **specializations** of E.

Information Systems Analysis and Design

csc340

# **Properties of Generalization**

- Every instance of a child is also an instance of the parent.
- Every property of the parent entity (attribute, identifier, relationship or other generalization) is also a property of a child entity. This property of generalizations is known as inheritance.

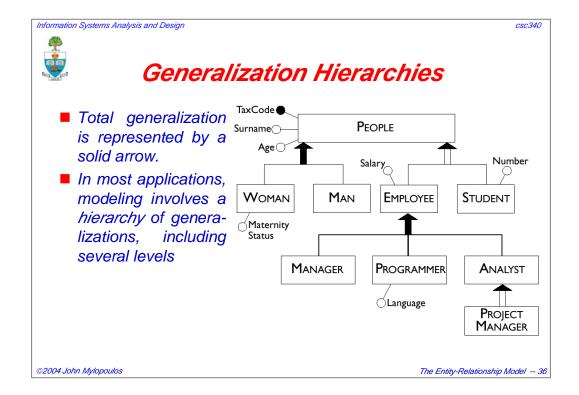

©2004 John Mylopoulos

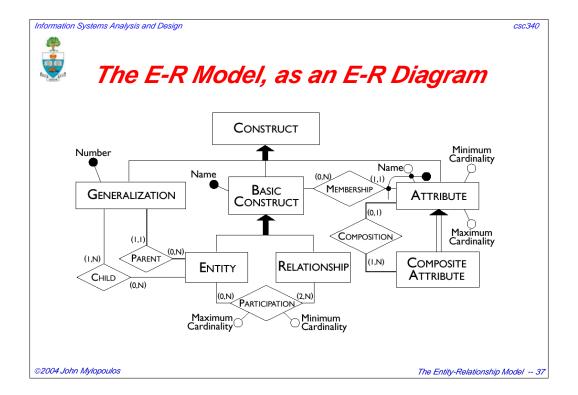

# Types of Generalizations

- A generalization is *total* if every instance of the parent is an instance of one of its children, otherwise it is *partial*.
- A generalization is **exclusive** if every instance of the parent is at most an instance of one child, otherwise **overlapping**.
- The generalization Person, of Man and Woman is total and exclusive (assuming a person is either a man or a woman).
- The generalization Vehicle of Automobile and Bicycle is partial and exclusive.
- The generalization Person of Student and Employee is partial and overlapping, because there are students who are also employed.

# Example

We wish to create a database for a company that runs training courses. For this, we must store data about the trainees and the instructors. For each course participant (about 5,000), identified by a code, we want to store her social security number, surname, age, sex, place of birth, employer's name, address and telephone number, previous employers (and periods employed), the courses attended (there are about 200 courses) and the final assessment for each course. We need also to represent the seminars that each participant is attending at present and, for each day, the places and times the classes are held.

Each course has a code and a title and any course can be given any number of times. Each time a particular course is given, we will call it an 'edition' of the course. For each edition, we represent the start date, the end date, and the number of participants. If a trainee is self-employed, we need to know her area of expertise, and, if appropriate, her title. For somebody who works for a company, we store the level and position held. For each instructor (about 300), we will show the surname, age, place of birth, the edition of the course taught, those taught in the past and the courses that the tutor is qualified to teach. All the instructors' telephone numbers are also stored. An instructor can be permanently employed by the training company or freelance.

# Glossary Example

Term	Description	Synonym	Links
Trainee	Participant in a course. Can be an employee or self-employed.	Participant	Course, Company
Instructor	Course tutor. Can be freelance.	Tutor	Course
Course	Course offered. Can have various editions.	Seminar	Instructor, Trainee
Company	Company by which a trainee is employed or has been employed.		Trainee

# Structuring of Requirements (I)

#### Phrases of a general nature

We wish to create a database for a company that runs training courses. We wish to maintain data for the trainees and the instructors.

#### Phrases relating to trainees

For each trainee (about 5000), identified by a code, the database will hold the social security number, surname, age, sex, town of birth, current employer, previous employers (along with the start date and the end date of the period employed), the editions of the courses the trainee is attending at present and those he or she has attended in the past, with the final marks out of ten.

#### Phrases relating to the employers of trainees

For each employer of a trainee the database will store name, address and telephone number.

©2004 John Mylopoulos

The Entity-Relationship Model -- 43

Information Systems Analysis and Design

csc340

# Structuring of Requirements (II)

#### Phrases relating to courses

For each course (about 200), we will hold the name and code. Each time a particular course is given, we will call it an 'edition' of the course. For each edition, we will hold the start date, the end date, and the number of participants. For the editions currently in progress, we will hold the dates, the classrooms and the times in which the classes are held.

#### Phrases relating to specific types of trainee

For a trainee who is a self-employed professional, we will hold the area of expertise and, if appropriate, the professional title. For a trainee who is an employee, we will hold the level and position held.

#### Phrases relating to instructors

For each instructor (about 300), we will hold surname, age, town of birth, all telephone numbers, the edition of courses taught, those taught in the past and the courses the instructor is qualified to teach. The instructors can be permanently employed by the training company or can be freelance.

©2004 John Mylopoulos

# Operational Requirements

- operation 1: insert a new trainee including all her data (to be carried out approximately 40 times a day);
- operation 2: assign a trainee to an edition of a course (50 times a day);
- operation 3: insert a new instructor, including all his or her data and the courses he or she is qualified to teach (twice a day);
- operation 4: assign a qualified instructor to an edition of a course (15 times a day);
- operation 5: display all the information on the past editions of a course with title, class timetables and number of trainees (10 times a day);
- operation 6: display all the courses offered, with information on the instructors who are qualified to teach them (20 times a day);
- operation 7: for each instructor, find the trainees for all the courses he or she is teaching or has taught (5 times a week);
- operation 8: carry out a statistical analysis of all the trainees with all the information about them, about the editions of courses they have attended and the marks obtained (10 times a month).

The Entity-Relationship Model -- 45

Information Systems Analysis and Design

csc340

# **Solution** Serial Serial With the ER Model

- Design choices: Should a concept be modeled as an entity, an attribute, or a relationship?
- Constraints on the ER Model: A lot of data semantics can (and should) be captured; but some constraints cannot be captured by ER diagrams.

©2004 John Mylopoulos

### Some Rules of Thumb

- If a concept has significant properties and/or describes classes of objects with an autonomous existence, it is appropriate to represent it as an entity.
- If a concept has a simple structure, and has no relevant properties associated with it, it is convenient to represent it with an attribute of another concept to which it refers.
- If a concept provides a logical link between two (or more) entities, it is convenient to represent it with a relationship.
- If one or more concepts are particular cases of another concept, it is convenient to represent them in terms of a generalization relationship.

©2004 John Mylopoulos

The Entity-Relationship Model -- 47

Information Systems Analysis and Design

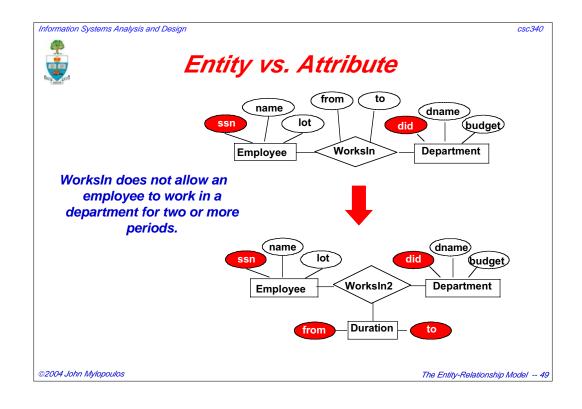

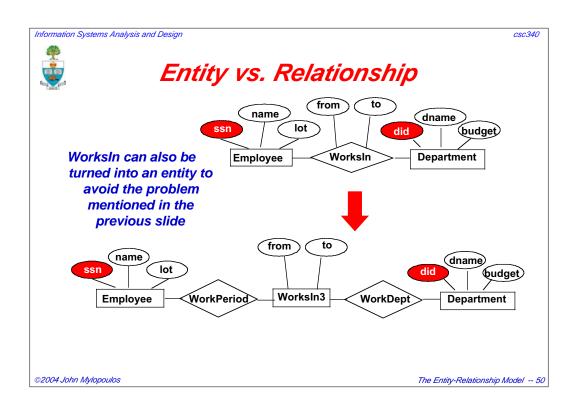

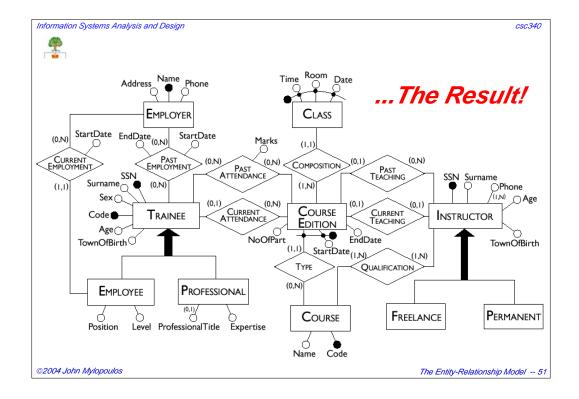

# **Examples**

- Consider **address** of a trainee. Is it an entity or relationship?
- Consider address for a telephone company database, which has to keep track of how many and what type of phones are available in any one household, who lives there (there may be several phone bills going to the same address) etc.
- How do we represent employment of a trainee by a particular employer?
- How do we represent a course edition?

©2004 John Mylopoulos

csc340

# Documentation of an E-R Schema -The Data Dictionary Revisited

- An Entity-Relationship schema is rarely sufficient by itself to represent all the aspects of an application in detail.
- It is therefore important to complement every E-R schema with support documentation, which can facilitate the interpretation of the schema itself and describe properties of the data that cannot be expressed directly by the constructs of the model.
- A widely-used documentation concept for conceptual schemas is the **business rule**.

©2004 John Mylopoulos

### **Business Rules**

- Business rules are used to describe the properties of an application, e.g., the fact that an employee cannot earn more than his or her manager.
- A business rule can be:
  - ✓ the description of a concept relevant to the application (also known as a business object),
  - ✓ an *integrity constraint* on the data of the application,
  - ✓ a *derivation rule*, whereby information can be derived from other information within a schema.

©2004 John Mylopoulos

The Entity-Relationship Model -- 53

Information Systems Analysis and Design

# The Data Dictionary

- Descriptive business rules can be organized as a data dictionary. This is made up of two tables: the first describes the entities of the schema, the others describes the relationships.
- Business rules that describe constraints can be expressed in the following form:
  - <concept> must/must not <expression on concepts>
- Business rules that describe derivations can be expressed in the following form:
  - <concept> is obtained by <operations on concepts>

©2004 John Mylopoulos

# Example of a Data Dictionary

Entity	Description	Attributes	Identifier
EMPLOYEE	Employee working in the company.	Code, Surname, Salary, Age	Code
PROJECT	Company project on which employees are working.	Name, Budget, ReleaseDate	Name

Description	Entities involved	Attributes
Associate a manager with a department.	Employee (0,1), Department (1,1)	
Associate an employee with a department.	Employee (0,1) Department (1,N)	StartDate
	Associate a manager with a department.  Associate an employee with a department.	Associate a manager with a department.  Associate an employee with a department.  Employee (0,1), Department (1,1)  Employee (0,1) Department (1,N)

©2004 John Mylopoulos

The Entity-Relationship Model -- 55

Information Systems Analysis and Design

csc340

# Examples of Business Rules

#### **Constraints**

**(BR1)** The manager of a department must belong to that department.

**(BR2)** An employee must not have a salary greater than that of the manager of the department to which he or she belongs.

**(BR3)** A department of the Rome branch must be managed by an employee with more than 10 years' employment with the company.

**(BR4)** An employee who does not belong to a particular department must not participate in any project.

....

#### **Derivations**

**(BR5)** The budget for a project is obtained by multiplying the sum of the salaries of the employees who are working on it by 3.

....

©2004 John Mylopoulos

# ER vs Class Diagrams

- ER diagrams allow N-ary relationships, N≥2; Class diagrams only allow binary relationships.
- ER diagrams allow multi-valued attributes, class diagrams do not.
- ER diagrams allow the specification of identifiers (an oftenencountered type of constraint), class diagrams do not.
- Class diagrams allow dynamic classification, but ER diagrams do not.
- Class diagrams can have associated methods, constraints and pre/post-conditions.

©2004 John Mylopoulos
