

# Pointers and Arrays

## – Recall the pointer syntax:

- `char *cptr;`
  - declares a pointer to a char
  - allocates space to store a pointer to a char
- `char c = 'a';`
- `cptr = &c;`
  - `cptr` gets the value of the address of `c`
  - the value stored at the memory location referred to by `cptr` is the address of the memory location referred to by `c`;
- `*cptr = 'b';` - dereference `cptr`
  - the address stored at `cptr` identifies the memory location where `'b'` will be stored.

# Pointers and Arrays

→ `char *cptr;`  
→ `char c = 'a';`  
→ `cptr = &c;`  
→ `*cptr = 'b';`

Symbol Table

|      |           |
|------|-----------|
| cptr | 0x80493e0 |
| c    | 0x80494dc |

0x80493e0

0x80494dc

# Arrays vs. Pointers

- An array name in expression context decays into a pointer to the zero'th element.

- E.g.

```
int a[3] = {1, 3, 5};  
int *p = a;  p = &a[0];  
p[0] = 10;  
printf( "%d %d\n", a[0], *p );
```

# Example

```
int a[4] = {0, 1, 2, 3};  
int *p = a;  
int i = 0;
```

```
for(i = 0; i < 4; i++) {  
    printf("%d\n", *(p + i));  
}
```

$(*p) == a[0]$

$*(p + 1) == a[1]$

$*(p + 2) == a[2]$

$*(p + 3) == a[3]$

|   |
|---|
|   |
| 0 |
| 1 |
| 2 |
| 3 |
|   |

Why does adding 1 to `p` move it to the next spot for an int, when an int is 4 bytes?

# Pointer Arithmetic

- Pointer arithmetic respects the type of the pointer.

- E.g.,

```
int i[2] = {1, 2};
```

```
int *ip;
```

```
ip = i;
```

```
*(ip + 1) += 2;
```

(really adds 4 to `ip`)

```
char c[2] = {'a', 'z'};
```

```
char *cp;
```

```
cp = c;
```

```
*(cp + 1) = 'b';
```

(really adds 1 to `cp`)

# Passing Arrays as Parameters

```
int main()  
{  
    int i[3] = {10, 9, 8};  
    printf("sum is %d\n", sum(i)); /*??*/  
}  
int sum( What goes here? ) {  
}
```

- What is being passed to the function is the name of the array which decays to a pointer to the first element – a pointer of type int.

# Passing Arrays as Parameters

```
int sum( int *a ) {  
    int i, s = 0;  
    for(i = 0; i < ??; i++)  
        s += a[i];    /* this is legal */  
}
```

- How do you know how big the array is?
- Remember that arrays are not objects, so knowing where the zero'th element of an array is does not tell you how big it is.
- Pass in the size of the array as another parameter.

# Array Parameters

```
int sum(int *a, int size)
```

- Also legal is

```
int sum(int a[], int size)
```

- Many advise against using this form.
  - You really are passing a pointer-to-int not an array.
  - You still don't know how big the array is.
  - Outside of a formal parameter declaration `int a[];` is illegal
- `int a;` and `int a[10];` are completely different things

# Multi-dimensional arrays

- Remember that memory is a sequence of bytes.

```
int a[3][3] = { { 0, 1, 2 },  
                { 3, 4, 5 },  
                { 6, 7, 8 } };
```

- Arrays in C are stored in row-major order
- row-major access formula

$x[i][j] == *(x + i * n + j)$

where  $n$  is the row size of  $x$

But use array notation!

# Summary

- The name of an array can also be used as a pointer to the zero'th element of the array.
- This is useful when passing arrays as parameters.
- Use array notation rather than pointer arithmetic whenever you have an array.
