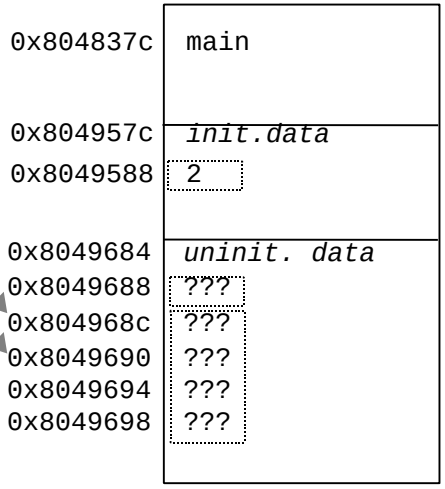
Static Allocation

- Recall: static allocation happens at compile time based on variable definitions.

```
int x = 2;
int a[4];
int *b;

int main() {}
```



```
SYMBOL TABLE:
main    0x804837c .text  f9
x       0x8049588 .data  04
b       0x8049688 .bss   04
a       0x804968c .bss   10
```

Dynamic Memory Allocation

- In Java,

```
Set s; // Memory is allocated for pointer s
// Memory is allocated for object
s = new HashSet();
```

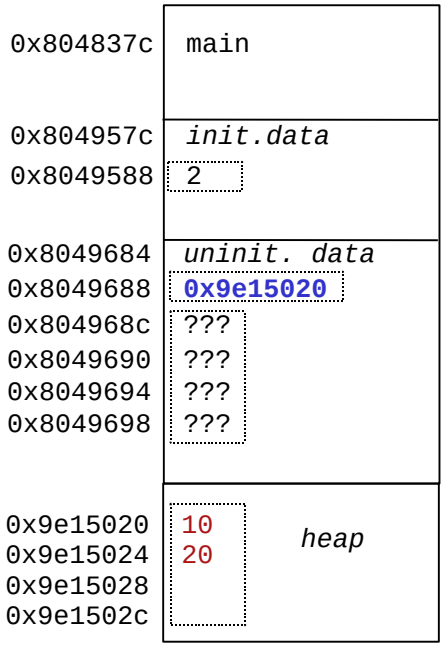
- In C,

```
int *a;  /* Memory is allocated for pointer a */
/* Memory is allocated for a to point to */
a = (int *)malloc(10 * sizeof(int));
```

Dynamic Allocation

```
int x = 2;
int a[4];
int *b;

int main() {
  b = (int *)malloc( 4 *
                sizeof(int));
  b[0] = 10;
  b[1] = 20;
}
```



SYNOPSIS

#include <stdlib.h>

void *calloc(size_t nmemb**, size_t** size**);**
void *malloc(size_t size**);**
void free(void *ptr**);**
void *realloc(void *ptr**, size_t** size**);**

DESCRIPTION

malloc() allocates size bytes and returns a pointer to the allocated memory. The memory is not cleared.

free() frees the memory space pointed to by ptr, which must have been returned by a previous call to **malloc(), calloc()** or **realloc()**. Otherwise, or if **free(**ptr**)** has already been called before, undefined behaviour occurs. If ptr is **NULL**, no operation is performed.

malloc

```
void *malloc(size_t size);
```

- Some things you haven't seen yet:

  `void *`
  - A generic pointer type that can point to memory of any type.

  `size_t`
  - A type defined by the standard library as the type returned by `sizeof`.
  - The type is `unsigned int`.

malloc

- Usually cast the return value of malloc to the type you want.

```
int *i = (int *)malloc(sizeof(int));
char *c = (char *)malloc(NAME_SIZE);
```

- sizeof works on types, and knows type of expressions.

```
double *d = (double *)malloc(5*sizeof(*d));
```

- Be careful to allocate the correct number of bytes.
- E.g., `int *i = (int *)malloc(1); /*wrong*/`
  - allocates 1 byte, not 1 int.

NULL pointers

- A function that returns a block of memory might fail to do so, in which case it returns a null pointer.
- NULL is a pre-processor variable defined in iolib.h (included from stdio.h) and other places
  - it is usually defined to be 0 (no program allocates anything at address 0x0)

De-allocating memory

```
int *a = (int *)malloc(10 * sizeof(int));
int b[10];
...
a = b;
```

- What is wrong with the last line? It compiles and runs fine.
- We have lost the pointer to the memory region allocated in the first line, so that space is now tied up until the program terminates.

⇨ Memory leak!

free()

- Before removing the last pointer to a memory region, you must explicitly deallocate it.
  - No garbage collection in C!

```
int *a = (int *)malloc(10 * sizeof(int));
int b[10];
...
free(a);
a = b;
```

Is a NULL after the free statement?
→ No, `free` cannot change the value of a parameter

Dangling pointers

```
int *a = (int *)malloc(10 * sizeof(int));
...
free(a);
printf("%d\n", a[0]); /* Error */
```

- Dereferencing a pointer after the memory it refers to has been freed is called a “dangling pointer”.
- Behaviour is undefined. Might:
  - appear to work
  - bogus data
  - program crash

Arrays of pointers

- Most obvious use is to get an array of strings.

```
#define LEN 4
char **strs =(char **)malloc(3*sizeof(char *));

for(i = 0; i < 3; i++) {
   strs[i] = (char *)malloc(LEN);
}
strs[0] = strncpy(strs[0], "209", LEN);
strs[1] = strncpy(strs[1], "369", LEN);
```

Tips

- Use a debugger and start to figure out what valid addresses look like.
- Check return values from library functions.
- Watch out for common errors:
  - forgetting to allocate memory when a pointer is declared.
