## Rule Ordering and Unification

1. rule ordering used in search
2. unification requires two instances of the same variable in the same rule to get the same value
3. unification does not require differently named variables to get different values: hene sibling(edward,edward).
4. all rules searched if requested by ';'

More on unification in a lecture to come...

## How Prolog Handles a Query

Trace it by hand
Example 1
Database:

1) ${ }^{\text {2) }}$ male (tom).
male $($ peter $)$.
2) male(peter).
3) 
4) 

fale(doug).
female (susan)
5) male(david).
6) parent (doug, susan).
8) parent (tom, william).
9) parent (doug, tom)
10) grandfather (GP, GC) :- male (GP),
parent (GP, X$),$
$\mathrm{parent}(\mathrm{X}, \mathrm{GC})$
Query
?- grandfather ( $\mathrm{X}, \mathrm{y}$ ).

22

## Trace it in Prolog

[trace] ?- grandfather (X, Y).
Call: (7) grandfather (_G283, _G284) ? creep
Ca11: (7) grandfather ( G283, - G284) ? creep
Cal1: (8) male(_G283) creep Exit: (8) male(-G283) ? creep
Exit: male(tom) ? creep
Call: (8) parent (tom, Lrep ) ? creep
Exit: (8) parent(tom, william) ? creep
Call: (8) parent (william, _G284)? creep
Call: (8) parent (william, -G284) ? creep
Fail: (8) parent(william, -G284) ? creep
Redo: (8) male (_G283)? creep
Exit: (8) male(peter)? creep
Call: (8) parent(peter, L205) ? creep
Fai1: (8) parent (peteter, Ler, L205) ? ? creep
Redo: (8) male(_G283)? Creep
Exit: (8) male (doug)?
Exit: (8) male(doug)? creep
Call: (8) parent (doug, -L205) ? creep
Exit: (8) parent(doug, susan)? creeep
Call: (8) parent(susan, G284)? crep
Call: (8) parent (susan, - 2284 ? ? creep
Fail: (8) parent(susan, -G284)? creep
Redo: (8) parent (doug, L205)? creep
Exit: (8) parent(dous,
Exit: (8) parent(doug, david)? creep
Call: (8) parent(david, G284)? creep
Call: (8) parent(ddavid, $\begin{aligned} & \text { G284)? Creep } \\ & \text { Fail: (8) parent(david, } \\ & \text { G284) ? creep }\end{aligned}$
Fail: (8) parent(david, -G284)? creep
Redo: (8) parent(doug, L205) ? creep
Redo: (8) parent (doug, L 205 ) ? cree
Exit: (8) parent (doug, tom)? creep
Exit: (8) parent (doug, tom)? creep
Call: (8) parent (tom, G284)? creep
Exit: (8) parent (tom, william) ? creep
Exit: (7) grandfather (doug, william)? creep $\mathrm{X}=\mathrm{doug}$
$\mathrm{Y}=\mathrm{william}$

## Prolog Search Trees

- Each node is an ordered list of goals.
- Each edge is labelled with the variable bindings that occurred due to applying a rule. (The binding are in effect throughout the subtree.)
- Each leaf represents either success or failure.

## Example 2

## Trace it by hand

## Database

1) male(albert).
2) female(alice).
3) male(edward).
4) 

female(victoria)
5) female(victoria).
${ }^{\text {6) }}$ 6) parent (victoria, edvard)
parent (victoria, edwara)
parent (albert, alice).
parent(victoria, alice).
sibling( $\mathrm{X}, \mathrm{Y}):-\mathrm{parent}(\mathrm{P}, \mathrm{X}), \quad$ parent( $\mathrm{P}, \mathrm{Y})$

## Query:

?- sibling(alice,Asib)
Asib = edward ;
Asib =alice;
Asib = edward;
Asib $=$ alice
Asib
No
No
?- sibling(Asib, alice).
Asib $=$ edward ;
Asib = edward ;
Asib $=$ edward ;
Asib = alice ;

## Trace it in Prolog

[trace] ?- sibling(alice, Asib) Call: (7) sibling(alice, G284) ? creep Cal1: (8) parent (LL205, alice)? creep
Exit: (8) parent (aloert ili) ? Exit: (8) parent (albert, alice) ? creep Exit: (8) parent (albert, edarard ? creep
Exit: (7) sibling(alice, edward) ? creep

Asib = edward ;
Redo: (8) parent(albert, - G284) ? cree Exit: (8) parent (albert, alice) ? creep
Exit: (7) sibling(alice, alice)?

Asib = alice
Redo: (8) parent(_L205, alice)? creep
Exit: (8) parent (victoria alice)? Exit: (8) parent(victoria, alice) ? creep
Cal1: (8) parent(victoria, - G284)? creep
Exit: (8) parent(victoria, edward)? cre
Exit: (7) sibling(alice, edvard)? creep
Asib = edward ;
Redo: (8) parent(victoria, -G284) ? creep Exit: (8) parent(victoria, alice)? creep
Exit: (7) sibling(alice, alice) ? creep
Asib = alice

The Anonymous Variable
If a rule has a variable that appears only one that variable is called a "singleton variable".

Its value doesn't matter - it doesn't have to match anything elsewhere in the rule.
isamother(X) :- female (X), parent(X, Y).
Such a variable consumes resources at run time.

We can replace it with " -", the anonymous variable. It matches anything.

If we don't, Prolog will warn us

## Logic Programming vs. Prolog

Logic Programming: Nondeterministic

- Arbitrarily choose rule to expand first
- Arbitrarily choose subgoal to to explore first
- Results don't depend on rule and subgoal ordering

## Prolog: Deterministic

- Expand first rule first
- Explore first subgoal first
- Results may depend on rule and subgoa ordering

## Procedural Semantics of Prolog

Notice the recursion in this algorithm: "find" calls "find". This reasoning is recursively applied until we reach rules that are facts.

This process is called Backward Chaining
?- cousin(X,jane). \% a query
Rule and Goal Ordering:

- There are two rules for cousin
- Which rule do we try first?
- Each rule for cousin has several subgoals
- Which subgoal do we try first?

Logic Programming vs. Prolog
cousin $(\mathrm{X}, \mathrm{Y})$ :- $\operatorname{parent}(\mathrm{W}, \mathrm{X}), \operatorname{sister}(\mathrm{W}, \mathrm{Z})$ parent $(Z, Y)$.
$\operatorname{cousin}(X, Y)$ :- $\operatorname{parent}(W, X), \operatorname{brother}(W, Z)$, parent $(Z, Y)$.

- Which subgoal do we try firs?

## Let's Write Some Code

Write these predicates:

1. uncle
2. aunt
3. nephew
4. niece
5. grandparent
6. ancestor

Code we develop in class will be posted on the Web site as text so that you can load and run it.
