1

Prolog vs Scheme

In Scheme, we program with **functions** ("procedures").

- A function's arguments are different from the function's value.
- Give a single Scheme function, we can only ask one kind of question:

Here are the argument values; tell me what is the function's value.

In Prolog, we program with relations.

- There is no bias; all arguments are the same.
- Given a single Prolog predicate, we can ask many kinds of question;

Here are some of the argument values; tell me what the others have to be in order to make a true statement.

Logic Programming and Prolog

Logic programming languages are not procedural or functional.

- · Specify relations between objects
- larger (3,2)
- father (tom. jane)
- . Separate logic from control:
 - Programmer declares what facts and relations are true
- System determines how to use facts to solve problems.
- System instantiates variables in order to make relations true!
- Computation engine: theorem-proving and recursion (Unification, Resolution, Backward Chaining, Backtracking)
 - Higher-level than imperative languages

2

- Logic Programming

 A program consists of facts and rules.
- Running a program means asking queries.
- The language tries to find one way (or more) to prove that the query is true.
- This may have the side effect of freezing variable values.
- The language determines how to do all of this, not the program
- How does the language do it? Using unlication, resolution, and backtracking.

Jumping Right In

Suppose we state these facts:

male(albert). parent(albert,edward). female(alice). parent(victoria,edward). male(edward). parent(albert,alice). female(victoria). parent(victoria,alice).

We can then make queries:

```
?- male(albert).
Yes
?- male(victoria).
No
?- female(Person).
Person = alice;
Person = victoria;
No
?- parent(Person, edward).
Person = albert;
Person = victoria;
No
?- parent(Person, edward), female(Person).
Person = victoria;
No
```

We can also state rules, such as this one:

Then the queries become more interesting:

```
Then the queries become m

?- sibling(albert, victoria).
No

?- sibling(edward, Sib).
Sib = edward;
Sib = alice;
Sib = edward;
Sib = alice;
No
```

?- parent (Person, edward).

Person = albert; Person = victoria;

--- edit family.P and remove parent(albert,edward). ---

?- ['family'].

% family compiled 0.00 sec, 5,200 bytes Yes

?- parent (Person, edward).

Person = victoria;

?- halt.

9

Some Prolog Syntax

Lexical Rules:

- Variables are capitalized.
- Constants begin with a lower case letter.
- Predicate names begin with a lower case letter

Simplified Grammar:

Note: No blank between predicate name and opening bracket.

10

Prolog Queries

A query is a proposed fact that is to be proven.

- If the query has no variables, returns yes/no.
- If the query has variables, returns appropriate values of variables (called a substitution).

11

Horn Clauses (Rules)

A Horn Clause is: $c \leftarrow h_1 \wedge h_2 \wedge h_3 \wedge \dots \wedge h_n$

- Antecedents: conjunction of zero or more conditions which are atomic formulae in predicate logic
- Consequent: an atomic formula in predicate logic

Meaning of a Horn clause:

- "The consequent is true if the antecedents are all true"
- ullet c is true if h_1 , h_2 , h_3 , \dots , an bla_n are all true

Horn Clause Terminology

- Horn Clause = Clause
- Consequent = Goal = Head
- Antecedents = Subgoals = Tail
- Horn Clause with No Tail = Fact
- Horn Clause with Tail = Rule

In Prolog, a Hom clause

$$c \leftarrow h_1 \wedge ... \wedge h_n$$

is written

$$c:=h_1, h_n$$

Syntax elements: ':-' ',' '.'

Prolog Horn Clause Examples

A Horn clause with no tail:

male(albert).

I.e., a fact: albert is a male dependent on no other conditions

A Horn clause with a tail:

father(albert,edward):male(albert), parent(albert,edward).

I.e., a rule: albert is the father of edward if albert is male and albert is a parent of edward's.

Meaning of Prolog Rules Without Variables

A prolog rule must have this form:

$$c := a_1, \quad a_2, \quad a_3, \quad \cdots, \quad a_n.$$
 which means in logic:

$$a_1 \wedge a_2 \wedge a_3 \wedge \cdots \wedge a_n \rightarrow c$$
.

Restrictions

 There can be zero or more antecedents, but they are conjoined; we cannot disjoin the

15

• There cannot be more than 1 consequent.

12

13

14

Bending the Restrictions

Why Can't We Disjoin Consequents?

Horn Clauses with Variables

Getting disjoined antecedents

Example: $a_1 \lor a_2 \lor a_3 \lor \rightarrow c$.

Solution:

Getting more than 1 consequent, conjoined

Example: $a_1 \wedge a_2 \wedge a_3 \rightarrow c_1 \wedge c_2$.

Solution:

Getter more than 1 consequent, disjoined

Example: $a_1 \wedge a_2 \wedge a_3 \rightarrow c_1 \vee c_2$.

Solution:

16

Why did the designers of Prolog disallow this?

Variables may appear in the antecedents and consequent of a Horn clause:

• $c(X_1,\ldots,X_n)$:- $h(X_1,\ldots,X_n)$.

Logic Review

"For all values of X_1,\ldots,X_n , the formula $c(X_1,\ldots,X_n)$ is true if the formula $h(X_1,\ldots,X_n)$ is true"

• $c(X_1,\ldots,X_n)$:- $h(X_1,\ldots,X_n,Y_1,\ldots,Y_k)$.

"For all values of X_1,\ldots,X_n , the formula $c(X_1,\ldots,X_n)$ is true if there exist values of Y_1,\ldots,Y_k such that the formula $h(X_1,\ldots,X_n,Y_1,\ldots,X_n,Y_n)$ is true"

19

Meaning of Prolog Rules With Variables

Example:

isaMother(X) :- female(X), parent(X, Y).

Logic:

 $parent(X, Y) \land female(X) \supset isaMother(X).$

But this is meaningless without quantifiers for the variables.

The rule

A Prolog rule of this form $(n \ge 0, m \le n, k \ge o)$:

$$c(X_1,\cdots X_n):=a(X_1,\cdots X_m,Y_1,\cdots Y_k).$$

means:

 $\forall X_1, \cdots X_n$

$$[\exists Y_1, \cdots Y_k \ [a(X_1, \cdots X_m, Y_1, \cdots Y_k) \supset c(X_1, \cdots X_n)]]$$

Sample run

cdf% pl
Welcome to SWI-Prolog (Multi-threaded, Version 5.2.11).''
?- ['family'].

Warning: (,/family.pl:50):
Singleton variables: [Y]
% family compiled 0.00 sec, 5,528 bytes

?- isaMother(X).
X = victoria;
X = victoria;

No
