Design patterns

- We showed the structures of all the classic design patterns
- We explained some of them and their applications in OpenOME, Protégé and Eclipse
- For your exercise
  - Explain the MVC and plug-in patterns using the classic design patterns
  - Find more cases in OpenOME that can apply the design patterns
- The application of design patterns, can be called "refactoring"

1. What is refactoring?

- It is a new English word, can be used in part of speech for a noun (countable or uncountable), a verb …

- Its origin = Factoring

Factoring

- In *mathematics*, **factorization** or **factoring** is the decomposition of an object into an expression of smaller objects, or **factors**, which multiplied together give the original

- For example, the number 15 factors into *primes* as 3×5; and the *polynomial* $x^2 - 4$ factors as $(x - 2)(x + 2)$

Refactoring

- **Refactoring** is the process of rewriting written material to improve its *readability* or structure, with the explicit purpose of keeping its meaning or behavior.
    - The term is by analogy with the *factorization* of numbers and polynomials. For example, x^2 - 1 can be factored as $(x + 1)(x - 1)$, revealing an internal structure that was previously not visible (such as the two zeroes at +1 and -1). Similarly, in software refactoring, the change in visible structure can often reveal the "hidden" internal structure of the original code.

- Extracting common descriptions
  20 + 20 + 20 = (1 + 1 + 1) x 20 = 3 x 20

Software Refactoring

- Software refactoring = "*Restructuring* existing code by altering its internal structure without changing its external behavior"
  – adapted from Martin Fowler's book

More on definitions

Are the following activities refactorings?

- Adding new functionalities
- Fixing correctness bugs
- Tuning performance
- Patching security holes

When to apply refactorings

"Any fool can write code that a computer can understand. Good programmers write code that human can understand"

Bad code smells:

- Duplicate code (clones): *feature envy*
- Complex control, Long method

  use *Hammock graph*: single entry/single exit
  - Comments signal semantic distance
  - Conditional and loops

- Complex data, Long parameter list
- OO specific: large class, switch statements, parallel inheritance, middle man, message change, temporary fields, data class, etc.

The refactoring rhythms

- Development =
  (Adding features, Refactoring)*
- Refactoring = (Testing, Small Steps) *
- Small Steps = one of the refactoring types

2. Type of refactorings

"Putting things together when changes are together"

- Extract Methods
- Move Methods
- Rename Methods
- Replace Temp with Query
- Replace conditionals with polymorphism
- Replace Type code with State/Strategy
- Self Encapsulate Field
- *……*

3. Applications

- We use three examples to explain some basic refactorings
  - Extract method:
    - signalled by comments
    - single-entry, single-exit
    - increase the level of indirection
    - reduce the length of a method
    - increase the chance of reuse
  - Move method:
    - Place method together with the object, *Putting things together when changes are together*
  - Replace conditions with polymorphism
    - Switches are "hard code", polymorphism is better for extensibility in OO

Example 1 – Extract method

```
void f() {

    ...

    // Compute score

    score = a * b + c;

    score -= discount;

}
```

```
void f() {

    ...

    computeScore();

}

void computeScore() {

    score = a * b + c;

    score -= discount;

}
```

Example 2 – Move method

```
class Jar {
    ...
}
class RoboPacker {
    private bool isFragile(Jar foo) {
        switch(foo.material) {
        case GLASS: return true;
        case WOOD: return true;
        case TIN: return false;
        }
    }
}
```

```
class Jar {
    bool isFragile() {
        switch(material) {
        case GLASS: return true;
        case WOOD: return true;
        case TIN: return false;
} } }
class RoboPacker {
    private bool isFragile(Jar foo) {
        return foo.isFragile();
    }
}
```

Example 3 – Replace conditionals with polymorphism
```
class Jar {
    bool isFragile() {
        switch(material) {
        case GLASS:
            // complex glass calculation
        case WOOD:
            // complex wood calculation
        case TIN:
            // complex tin calculation
}}}
```

```
class Jar {
    bool isFragile() {
        return material.isFragile();
} }

interface Material { ... }
class GlassMaterial:Material { ... }
class WoodMaterial:Material { ... }
class TinMaterial:Material { ... }
```

4. Refactoring versus Tuning

- Refactoring aims at improve understandability and maintainability
- Tuning aims at improve performance
- They are both non-functional (no new features), but they are different
  - Refactoring can be harmful to performance
  - Tuning can be harmful to maintainability
- You need to know where are the bottlenecks

Your exercise

- Monitor the evolution of your software product by measured its metrics
  - Statically:
    complexity metrics: LOC, Halstead, McCabe
  - Dynamically:
    Performance metrics: time (clockticks, #instructions), space (cache misses, L1 instruction, L1 data, L2 cache, etc., memory footprint)

- Decide on which is the urgent non-functional task
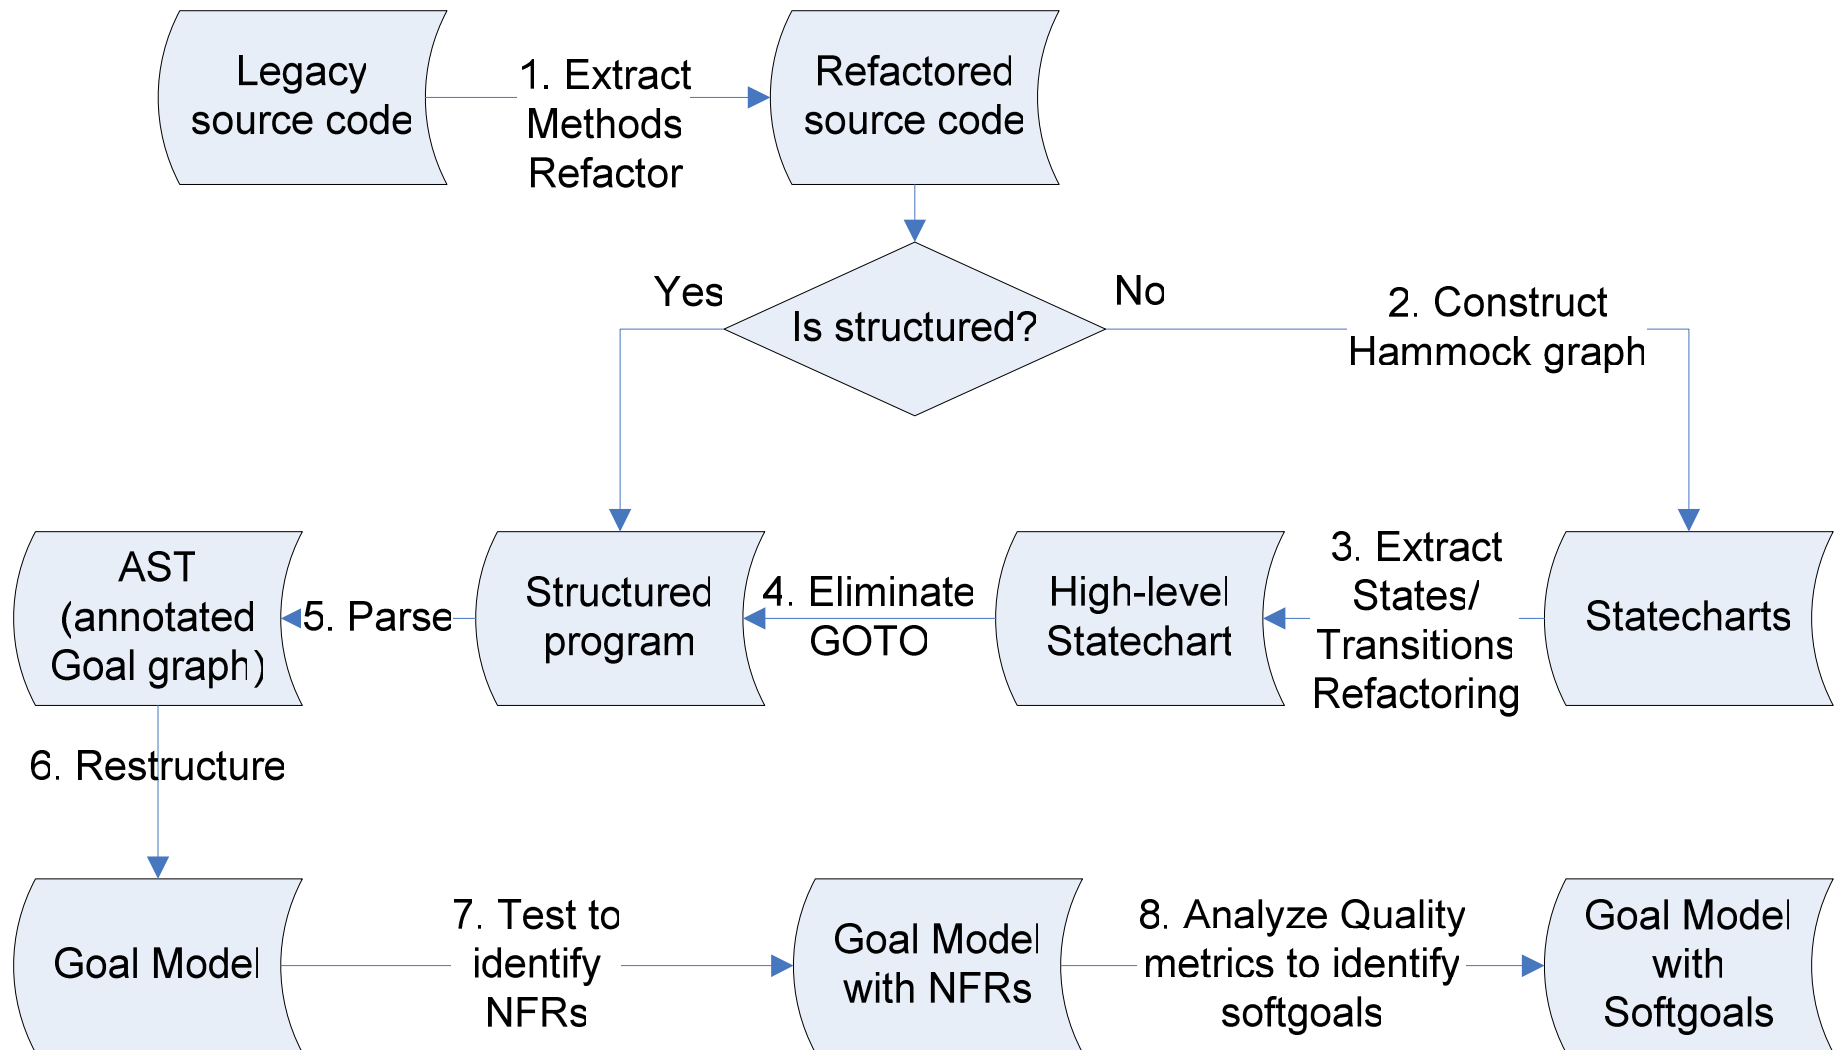

5. Refactoring into Requirements

Motivation to recover requirements from source code

- Requirements are lost in documentations, sadly, it is very common in the software development practices
- Legacy software code are not explained in documentation
- Mismatch between implementations and requirements

Huge gap in abstractions

Software Engineering II

A semi-automatic process

Legacy source code → **1. Extract Methods Refactor** → Refactored source code

Refactored source code → **Is structured?**

Is structured? — Yes → Structured program

Is structured? — No → **2. Construct Hammock graph** → Statecharts

Statecharts → **3. Extract States/ Transitions Refactoring** → High-level Statechart

High-level Statechart → **4. Eliminate GOTO** → Structured program

Structured program → **5. Parse** → AST (annotated Goal graph)

AST (annotated Goal graph) → **6. Restructure** → Goal Model

Goal Model → **7. Test to identify NFRs** → Goal Model with NFRs

Goal Model with NFRs → **8. Analyze Quality metrics to identify softgoals** → Goal Model with Softgoals

Example. Columba Refactoring

- Search "Java email client" in Google, you will find this software

- It is open-source

- It has 140 KLOC in Java

- It also has plug-in patterns

- First thing, we modify the code base to fit Eclipse development (moving packages, i.e., move all "src" subdirectories including plug-in projects under the same "src" directory)

A screenshot

Where to look at first?

- Secondly, we look for the main routine from the manifest in the JAR file

  Manifest-Version: 1.0

  Ant-Version: Apache Ant 1.6.2

  Created-By: 1.4.2_06-b03 (Sun Microsystems Inc.)

  Main-Class: org.columba.core.main.Main

  Sealed: false

  Class-Path: lib/usermanual.jar lib/junit.jar lib/lucene-1.3-final.jar
   lib/commons-cli-1.0.jar lib/jwizz-0.1.2.jar lib/plastic-1.2.0.jar li
   b/jhall.jar lib/forms-1.0.4.jar lib/ristretto-1.0_RC2.jar lib/jscf-0.
   2.jar lib/macchiato-1.0pre1.jar lib/frapuccino-1.0pre1.jar lib/winpac
   k.jar lib/jniwrap-2.4.jar lib/jdom.jar lib/jpim.jar lib/je.jar ${lib.
   jdic}

The Main routine

public static void main(String[] args) {

    Main.getInstance().run(args);

 }

  Thus we look at "run" routine, which has 81 lines of code

The Run routine

```
public void run(String args[]) {
1    ColumbaLogger.createDefaultHandler();
2    registerCommandLineArguments();
3    // handle commandline parameters
4    if (handleCoreCommandLineParameters(args)) {
5       System.exit(0);
6    }
7    // prompt user for profile
8    Profile profile = ProfileManager.getInstance().getProfile(path);
9    // initialize configuration with selected profile
10     new Config(profile.getLocation());
11     // if user doesn't overwrite logger settings with commandline arguments
12     // just initialize default logging
13
14     ColumbaLogger.createDefaultHandler();
15     ColumbaLogger.createDefaultFileHandler();
16
17     for ( int i=0; i<args.length; i++) {
18        LOG.info("arg["+i+"]="+args[i]);
19     }
20     …
```
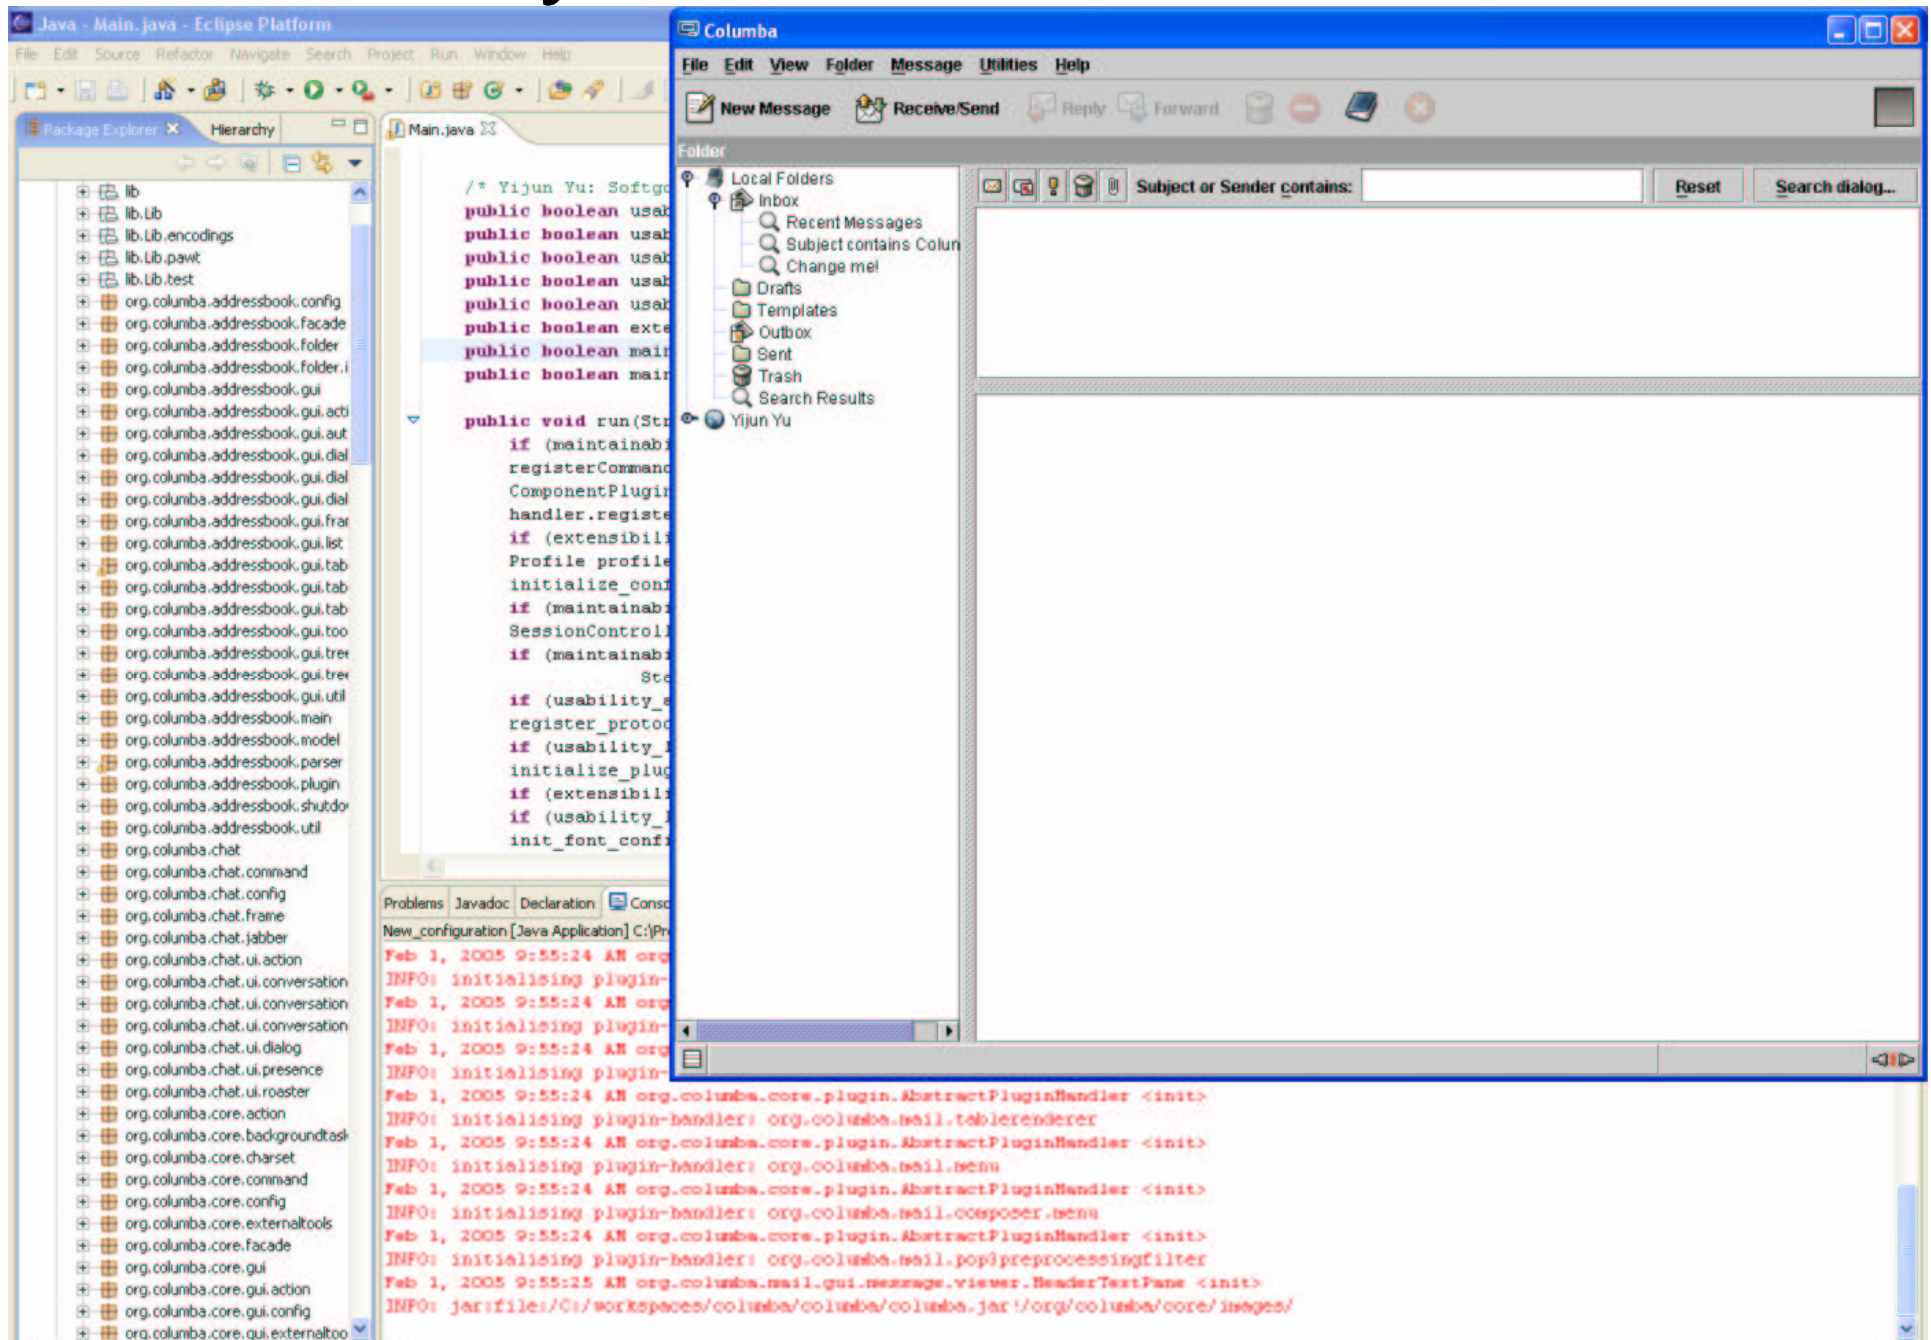

The Run routine refactored

```
public void run(String args[]) {
    ColumbaLogger.createDefaultHandler();
    registerCommandLineArguments();
    ComponentPluginHandler handler = register_plugins();
    handler.registerCommandLineArguments();
    handle_commandline_parameters(args);
    Profile profile = prompt_user_for_profile();
    initialize_configuration_with_selected_profile(profile);
    initialize_default_logging(args);
    SessionController.passToRunningSessionAndExit(args);
    enable_debugging_repaint_manager_for_swing_gui_access();
    StartUpFrame frame = show_splash_screen();
    register_protocol_handler();
    load_user_customized_language_pack();
    initialize_plugins(handler);
    load_plugins();
    set_look_and_feel();
    init_font_configurations();
    set_application_wide_font();
    hide_splash_screen(frame);
    handle_commandline_arguments_of_the_modules(handler);
    restore_frames_of_last_session();
    ensure_native_libraries_initialized();
    post_startup_of_the_modules(handler);
}
```

public boolean usability_look_and_feel = false;
public boolean usability_font_configuration = false;

    registerCommandLineArguments();
    ComponentPluginHandler handler = register_plugins();
     handler.registerCommandLineArguments();
    if (extensibility) handle_commandline_parameters(args);
    Profile profile = prompt_user_for_profile();
    initialize_configuration_with_selected_profile(profile);
    if (maintainability_logging) initialize_default_logging(args);
    SessionController.passToRunningSessionAndExit(args);
    if (maintainability_debugging) enable_debugging_repaint_manager_for_swing_gui_access();
        StartUpFrame frame = null;
    if (usability_assured_progress) { frame = show_splash_screen(); }
    register_protocol_handler();
    if (usability_language_customization) load_user_customized_language_pack();
    initialize_plugins(handler);
    if (extensibility) load_plugins();
    if (usability_look_and_feel) set_look_and_feel();
    init_font_configurations();
    if (usability_font_configuration) set_application_wide_font();
    if (usability_assured_progress) hide_splash_screen(frame);
    if (extensibility) handle_commandline_arguments_of_the_modules(handler);
    restore_frames_of_last_session();
    if (extensibility) ensure_native_libraries_initialized();
    if (extensibility) post_startup_of_the_modules(handler);
}
```

- The relation to restructuring, reengineering, design patterns, performance tuning, and requirements are explained
- Refactoring is not limited to OO software, that's the major different from the design patterns
- Refactoring is not aiming at all quality attributes, they are mainly for maintenance
- Refactoring is used to reveals new structures, thus it can be used to increase the level of abstraction gradually, leading to even requirements
- A lot research is coming …
