Contributions

Motivation FSAPLANNER and Plan Verification Contributions

< ロ > < 同 > < 三 > < 三 >

In this paper, we

- formally define a representation (FSA plan) for plans with loops;
- identify a class of (one-dimensional) planning problems whose plan correctness can be finitely verified;
- show that this verification algorithm enables FSAPLANNER to efficiently generate provably correct plans for this problem class.

The Situation Calculus Problem Representation Plan Representation Plan Correctness

# The Situation Calculus

The situation calculus is a multi-sorted logic for modeling dynamic environments, with sorts *situation*, *action* and *object*.

- S<sub>0</sub> is the unique initial situation, and do(a, s) is the situation obtained by performing action *a* in situation *s*.
- Changing properties modeled by fluents, *i.e.*, functions and predicates whose last argument is a situation term, *e.g.*,

 $loc(S_0) = home \land Loaded(do(load, S_0)).$ 

- Poss(a, s) is a special relation that holds iff action a is executable in situation s.
- SR(*a*, *s*) denotes the sensing result of action *a* when performed in situation *s*.

The Situation Calculus Problem Representation **Plan Representation** Plan Correctness

## Plan Representation

We use a finite-state automaton-like plan representation (called FSA plan), which can be viewed as a directed graph, where

- Each node represents a program state
  - One unique "start state"
  - One unique "final state"
  - Non-final states associated with action

The Situation Calculus Problem Representation **Plan Representation** Plan Correctness

### Plan Representation

To formalize FSA plans, we introduce a new sort "program states" with  $Q_0$  and  $Q_F$  being two constants, and a set of axioms FSA, consisting of

domain closure axioms for program states

$$(\forall q).q = Q_0 \lor q = Q_1 \lor \cdots \lor q = Q_n \lor q = Q_F;$$

unique names axioms for program states

$$Q_i \neq Q_j$$
 for  $i \neq j$ ;

action association axioms

$$\gamma(Q) = A;$$

transition axioms

$$\delta(Q,R)=Q'.$$

# **One-Dimensional Planning Problems**

A planning problem  $\langle \Sigma, G \rangle$  is *one-dimensional* if (intuitively)

- Only one fluent p (called the planning parameter) may take unbounded values from natural numbers;
- All fluents other than p take values from a finite set V.
- Initially, p may be arbitrary natural number.
- The only effect on p is to decrease it by one, *i.e.*,

$$p(do(a, s)) = x \equiv x = p(s) - 1 \land Dec(a) \lor$$
  
 $x = p(s) \land \neg Dec(a).$ 

• The only primitive test involving p in  $\Sigma$  and G is p = 0.

### Towards a Tighter Bound

- $N_0$  is exponential and thus impractical for many cases.
- We proposed an algorithmically obtained bound  $N_t$ , which is usually much smaller than  $N_0$ :
  - Verify that the FSA plan is correct for  $p = 0, 1, 2, \cdots$ .
  - Until for some  $N_t$ ,

$$\langle \vec{b}, N_t, Q_0 \rangle \rightarrow \langle \vec{b}^{\star}, u, q^{\star} \rangle \rightarrow \langle \vec{b}^{\star}, v, q^{\star} \rangle \rightarrow \text{SUCCESS}.$$

## Conclusion and Future Work

Planning with loops is an interesting and challenging problem. In this paper, we

- define a generalized plan representation that allows loops;
- give a formal notion of plan correctness under this representation;
- identify the class of one-dimensional problems whose correctness can be finitely verified;
- show that a planner based on this theoretical result efficiently generates provably correct plans for one-dimensional problems.
