### CSC 411: Lecture 06: Decision Trees

### Richard Zemel, Raquel Urtasun and Sanja Fidler

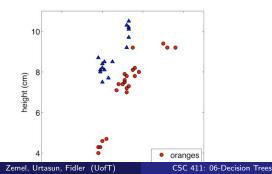

University of Toronto

#### • Decision Trees

- entropy
- information gain

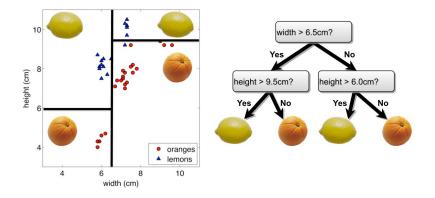

### Another Classification Idea

- We learned about linear classification (e.g., logistic regression), and nearest neighbors. Any other idea?
- Pick an attribute, do a simple test
- Conditioned on a choice, pick another attribute, do another test
- In the leaves, assign a class with majority vote
- Do other branches as well

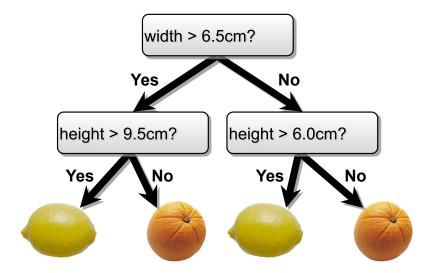

### Another Classification Idea

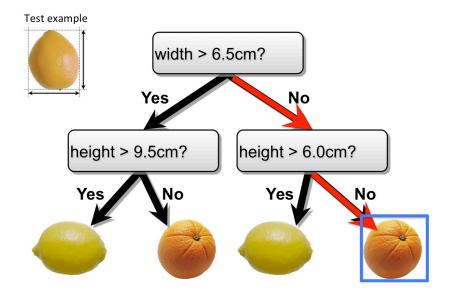

• Gives axes aligned decision boundaries

### Decision Tree: Example

## Decision Tree: Classification

## Example with Discrete Inputs

• What if the attributes are discrete?

Example	Input Attributes							Goal			
	Alt	Bar	Fri	Hun	Pat	Price	Rain	Res	Type	Est	WillWait
$\mathbf{x}_1$	Yes	No	No	Yes	Some	\$\$\$	No	Yes	French	0–10	$y_1 = Yes$
$\mathbf{x}_2$	Yes	No	No	Yes	Full	\$	No	No	Thai	30–60	$y_2 = \mathit{No}$
$\mathbf{x}_3$	No	Yes	No	No	Some	\$	No	No	Burger	0–10	$y_3 = Yes$
$\mathbf{x}_4$	Yes	No	Yes	Yes	Full	\$	Yes	No	Thai	10–30	$y_4 = Yes$
$\mathbf{x}_5$	Yes	No	Yes	No	Full	\$\$\$	No	Yes	French	>60	$y_5 = No$
$\mathbf{x}_{6}$	No	Yes	No	Yes	Some	\$\$	Yes	Yes	Italian	0–10	$y_6 = Yes$
$\mathbf{x}_7$	No	Yes	No	No	None	\$	Yes	No	Burger	0–10	$y_7 = No$
$\mathbf{x}_8$	No	No	No	Yes	Some	\$\$	Yes	Yes	Thai	0–10	$y_8 = Yes$
$\mathbf{x}_9$	No	Yes	Yes	No	Full	\$	Yes	No	Burger	>60	$y_9 = No$
$\mathbf{x}_{10}$	Yes	Yes	Yes	Yes	Full	\$\$\$	No	Yes	Italian	10–30	$y_{10} = No$
$\mathbf{x}_{11}$	No	No	No	No	None	\$	No	No	Thai	0–10	$y_{11} = No$
$\mathbf{x}_{12}$	Yes	Yes	Yes	Yes	Full	\$	No	No	Burger	30–60	$y_{12} = Yes$

1.	Alternate: whether there is a suitable alternative restaurant nearby.
2.	Bar: whether the restaurant has a comfortable bar area to wait in.
з.	Fri/Sat: true on Fridays and Saturdays.
4.	Hungry: whether we are hungry.
5.	Patrons: how many people are in the restaurant (values are None, Some, and Full).
6.	Price: the restaurant's price range (\$, \$\$, \$\$\$).
7.	Raining: whether it is raining outside.
8.	Reservation: whether we made a reservation.
9.	Type: the kind of restaurant (French, Italian, Thai or Burger).
10.	WaitEstimate: the wait estimated by the host (0-10 minutes, 10-30, 30-60, >60).

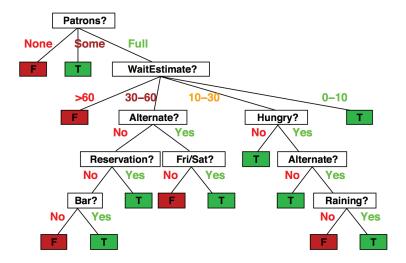

#### Attributes:

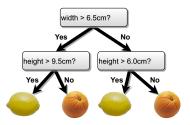

Zemel, Urtasun, Fidler (UofT)

CSC 411: 06-Decision Trees

### Decision Tree: Example with Discrete Inputs

• The tree to decide whether to wait (T) or not (F)

- Internal nodes test attributes
- Branching is determined by attribute value
- Leaf nodes are outputs (class assignments)

- Choose an attribute on which to descend at each level
- Condition on earlier (higher) choices
- Generally, restrict only one dimension at a time
- Declare an output value when you get to the bottom
- In the orange/lemon example, we only split each dimension once, but that is not required

## Decision Tree: Classification and Regression

- Each path from root to a leaf defines a region  $R_m$  of input space
- Let  $\{(x^{(m_1)}, t^{(m_1)}), \dots, (x^{(m_k)}, t^{(m_k)})\}$  be the training examples that fall into  $R_m$
- Classification tree:
  - discrete output
  - ▶ leaf value  $y^m$  typically set to the most common value in  $\{t^{(m_1)}, \ldots, t^{(m_k)}\}$
- Regression tree:
  - continuous output
  - leaf value  $y^m$  typically set to the mean value in  $\{t^{(m_1)}, \ldots, t^{(m_k)}\}$

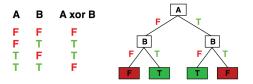

Note: We will only talk about classification

[Slide credit: S. Russell]

### Expressiveness

### • Discrete-input, discrete-output case:

- Decision trees can express any function of the input attributes
- E.g., for Boolean functions, truth table row  $\rightarrow$  path to leaf:

#### • Continuous-input, continuous-output case:

- Can approximate any function arbitrarily closely
- Trivially, there is a consistent decision tree for any training set w/ one path to leaf for each example (unless f nondeterministic in x) but it probably won't generalize to new examples

Need some kind of regularization to ensure more compact decision trees

[Slide credit: S. Russell]

### • How do we construct a useful decision tree?

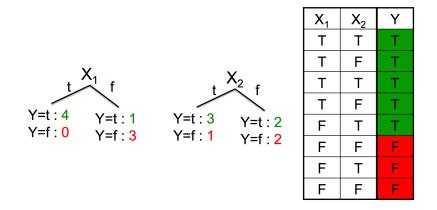

Learning the simplest (smallest) decision tree is an NP complete problem [if you are interested, check: Hyafil & Rivest'76]

- Resort to a greedy heuristic:
  - Start from an empty decision tree
  - Split on next best attribute
  - Recurse
- What is **best** attribute?
- We use information theory to guide us

[Slide credit: D. Sontag]

## Choosing a Good Attribute

• Which attribute is better to split on,  $X_1$  or  $X_2$ ?

**Idea:** Use counts at leaves to define probability distributions, so we can measure uncertainty

- Which attribute is better to split on,  $X_1$  or  $X_2$ ?
  - Deterministic: good (all are true or false; just one class in the leaf)
  - Uniform distribution: bad (all classes in leaf equally probable)
  - What about distributons in between?

Note: Let's take a slight detour and remember concepts from information theory

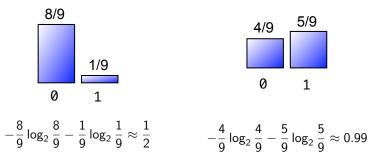

[Slide credit: D. Sontag]

```
Sequence 1:
000100000000000100...?
Sequence 2:
010101110100110101...?
     16
                            10
                        8
              versus
          2
     0
          1
                        0
                            1
```

# Quantifying Uncertainty

Entropy *H*:

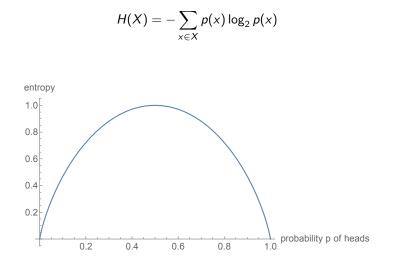

• How surprised are we by a new value in the sequence?

• How much information does it convey?

# Quantifying Uncertainty

## Entropy

### • "High Entropy":

- Variable has a uniform like distribution
- Flat histogram
- Values sampled from it are less predictable

### "Low Entropy"

- Distribution of variable has many peaks and valleys
- Histogram has many lows and highs
- Values sampled from it are more predictable

#### This slide seems wrong

[Slide credit: Vibhav Gogate]

## Entropy of a Joint Distribution

• Example:  $X = \{\text{Raining, Not raining}\}, Y = \{\text{Cloudy, Not cloudy}\}$ 

	Cloudy	Not Cloudy
Raining	24/100	1/100
Not Raining	25/100	50/100

$$H(X, Y) = -\sum_{x \in X} \sum_{y \in Y} p(x, y) \log_2 p(x, y)$$
  
=  $-\frac{24}{100} \log_2 \frac{24}{100} - \frac{1}{100} \log_2 \frac{1}{100} - \frac{25}{100} \log_2 \frac{25}{100} - \frac{50}{100} \log_2 \frac{50}{100}$   
 $\approx 1.56$  bits

## Specific Conditional Entropy

• Example:  $X = \{\text{Raining}, \text{Not raining}\}, Y = \{\text{Cloudy}, \text{Not cloudy}\}$ 

	Cloudy	Not Cloudy
Raining	24/100	1/100
Not Raining	25/100	50/100

• What is the entropy of cloudiness Y, given that it is raining?

$$H(Y|X = x) = -\sum_{y \in Y} p(y|x) \log_2 p(y|x)$$
  
=  $-\frac{24}{25} \log_2 \frac{24}{25} - \frac{1}{25} \log_2 \frac{1}{25}$   
 $\approx 0.24$  bits

• We used:  $p(y|x) = \frac{p(x,y)}{p(x)}$ , and  $p(x) = \sum_{y} p(x,y)$  (sum in a row)

	Cloudy	Not Cloudy
Raining	24/100	1/100
Not Raining	25/100	50/100

• The expected conditional entropy:

$$H(Y|X) = \sum_{x \in X} p(x)H(Y|X = x)$$
$$= -\sum_{x \in X} \sum_{y \in Y} p(x,y) \log_2 p(y|x)$$

## Conditional Entropy

• Example:  $X = \{\text{Raining, Not raining}\}, Y = \{\text{Cloudy, Not cloudy}\}$ 

	Cloudy	Not Cloudy
Raining	24/100	1/100
Not Raining	25/100	50/100

• What is the entropy of cloudiness, given the knowledge of whether or not it is raining?

$$H(Y|X) = \sum_{x \in X} p(x)H(Y|X = x)$$
  
=  $\frac{1}{4}H(\text{cloudy}|\text{is raining}) + \frac{3}{4}H(\text{cloudy}|\text{not raining})$   
 $\approx 0.75 \text{ bits}$ 

- Some useful properties:
  - H is always non-negative
  - Chain rule: H(X, Y) = H(X|Y) + H(Y) = H(Y|X) + H(X)
  - If X and Y independent, then X doesn't tell us anything about Y: H(Y|X) = H(Y)
  - But Y tells us everything about Y: H(Y|Y) = 0
  - By knowing X, we can only decrease uncertainty about Y: H(Y|X) ≤ H(Y)

	Cloudy	Not Cloudy
Raining	24/100	1/100
Not Raining	25/100	50/100

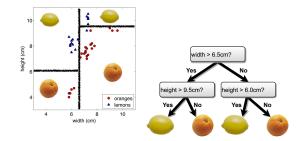

• How much information about cloudiness do we get by discovering whether it is raining?

$$IG(Y|X) = H(Y) - H(Y|X)$$
  

$$\approx 0.25 \text{ bits}$$

- Also called information gain in Y due to X
- If X is completely uninformative about Y: IG(Y|X) = 0
- If X is completely informative about Y: IG(Y|X) = H(Y)
- How can we use this to construct our decision tree?

## Constructing Decision Trees

- I made the fruit data partitioning just by eyeballing it.
- We can use the information gain to automate the process.
- At each level, one must choose:
  - 1. Which variable to split.
  - 2. Possibly where to split it.
- Choose them based on how much information we would gain from the decision! (choose attribute that gives the highest gain)

- Simple, greedy, recursive approach, builds up tree node-by-node
- 1. pick an attribute to split at a non-terminal node
- 2. split examples into groups based on attribute value
- 3. for each group:
  - if no examples return majority from parent
  - else if all examples in same class return class
  - else loop to step 1

### Back to Our Example

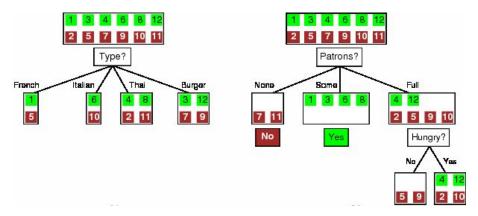

Example	Input Attributes									Goal	
	Alt	Bar	Fri	Hun	Pat	Price	Rain	Res	Type	Est	WillWait
$\mathbf{x}_1$	Yes	No	No	Yes	Some	\$\$\$	No	Yes	French	0–10	$y_1 = Yes$
$\mathbf{x}_2$	Yes	No	No	Yes	Full	\$	No	No	Thai	30–60	$y_2 = No$
$\mathbf{x}_3$	No	Yes	No	No	Some	\$	No	No	Burger	0–10	$y_3 = Yes$
$\mathbf{x}_4$	Yes	No	Yes	Yes	Full	\$	Yes	No	Thai	10–30	$y_4 = Yes$
$\mathbf{x}_5$	Yes	No	Yes	No	Full	\$\$\$	No	Yes	French	>60	$y_5 = No$
$\mathbf{x}_6$	No	Yes	No	Yes	Some	\$\$	Yes	Yes	Italian	0–10	$y_6 = Yes$
$\mathbf{x}_7$	No	Yes	No	No	None	\$	Yes	No	Burger	0–10	$y_7 = No$
$\mathbf{x}_8$	No	No	No	Yes	Some	\$\$	Yes	Yes	Thai	0–10	$y_8 = Yes$
$\mathbf{x}_9$	No	Yes	Yes	No	Full	\$	Yes	No	Burger	>60	$y_9 = No$
$\mathbf{x}_{10}$	Yes	Yes	Yes	Yes	Full	\$\$\$	No	Yes	Italian	10–30	$y_{10} = No$
$\mathbf{x}_{11}$	No	No	No	No	None	\$	No	No	Thai	0–10	$y_{11} = No$
$\mathbf{x}_{12}$	Yes	Yes	Yes	Yes	Full	\$	No	No	Burger	30–60	$y_{12} = Yes$

Alternate: whether there is a suitable alternative restaurant nearby.
Bar: whether the restaurant has a comfortable bar area to wait in.
Fri/Sat: true on Fridays and Saturdays.
Hungry: whether we are hungry.
Patrons: how many people are in the restaurant (values are None, Some, and Full).
Price: the restaurant's price range (\$, \$\$, \$\$\$).
Raining: whether it is raining outside.
Reservation: whether we made a reservation.
Type: the kind of restaurant (French, Italian, Thai or Burger).
WaitEstimate: the wait estimated by the host (0-10 minutes, 10-30, 30-60, >60).

[from: Russell & Norvig]

Attributes:

### Attribute Selection

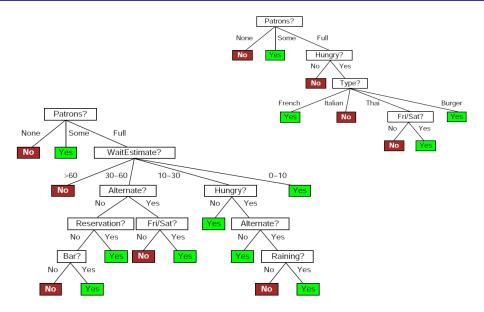

$$IG(Y) = H(Y) - H(Y|X)$$

$$IG(type) = 1 - \left[\frac{2}{12}H(Y|\text{Fr.}) + \frac{2}{12}H(Y|\text{It.}) + \frac{4}{12}H(Y|\text{Thai}) + \frac{4}{12}H(Y|\text{Bur.})\right] = 0$$

$$IG(Patrons) = 1 - \left[\frac{2}{12}H(0,1) + \frac{4}{12}H(1,0) + \frac{6}{12}H(\frac{2}{6},\frac{4}{6})\right] \approx 0.541$$

### Which Tree is Better?

- Not too small: need to handle important but possibly subtle distinctions in data
- Not too big:
  - Computational efficiency (avoid redundant, spurious attributes)
  - Avoid over-fitting training examples
- Occam's Razor: find the simplest hypothesis (smallest tree) that fits the observations
- Inductive bias: small trees with informative nodes near the root

### Problems:

- You have exponentially less data at lower levels
- Too big of a tree can overfit the data
- Greedy algorithms don't necessarily yield the global optimum
- In practice, one often regularizes the construction process to try to get small but highly-informative trees
- Decision trees can also be used for regression on real-valued outputs, but it requires a different formalism

### **K-Nearest Neighbors**

- Decision boundaries: piece-wise linear
- Test complexity: non-parametric, few parameters besides (all?) training examples

#### **Decision Trees**

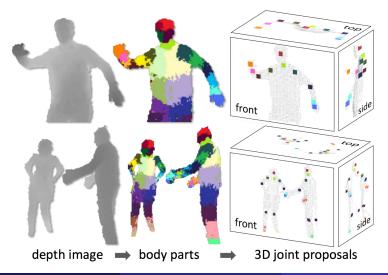

- Decision boundaries: axis-aligned, tree structured
- Test complexity: attributes and splits

• Decision trees are in XBox

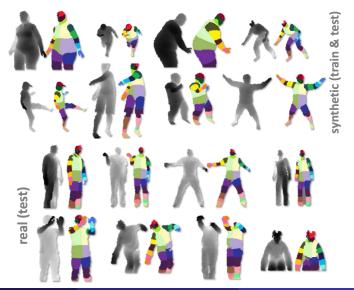

[J. Shotton, A. Fitzgibbon, M. Cook, T. Sharp, M. Finocchio, R. Moore, A. Kipman, A. Blake. Real-Time Human Pose

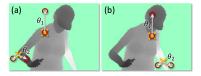

• Decision trees are in XBox: Classifying body parts

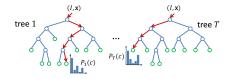

• Trained on million(s) of examples

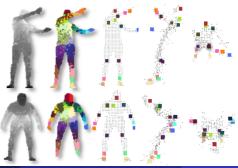

• Trained on million(s) of examples

### Results:

- Can express any Boolean function, but most useful when function depends critically on few attributes
- Bad on: parity, majority functions; also not well-suited to continuous attributes
- Practical Applications:
  - Flight simulator: 20 state variables; 90K examples based on expert pilot's actions; auto-pilot tree
  - Yahoo Ranking Challenge
  - Random Forests: Microsoft Kinect Pose Estimation
