

## CSC 121 — Lab Exercise 10

This is a non-credit exercise, which you do not hand in.

You may work on your own or together with another student, as you please.

In this lab, you will extend the example of object-oriented programming in the Week 11 lecture slides, by changing the representation of box objects, and adding a new “plus” object.

The functions from the lecture slides are available at

<http://www.cs.utoronto.ca/~radford/csc121/draw.r>

and the script that was used (in slightly different form) to produce the results in the lecture slides is at

<http://www.cs.utoronto.ca/~radford/csc121/drawscript.r>

As a first exercise, modify the functions for the “box” class to represent a box by a list whose elements are the same as the arguments of the `new_box` function. This may require changing `new_box`, `draw.box`, `rescale.box`, and `translate.box`. But it should not require any change to the R code that uses boxes, in the script file.

As a second exercise, try to add a new “plus” object, which looks like a plus sign. You should write a `new_plus` function that creates an object of class “plus”, given the  $x$  and  $y$  coordinates of the centre of the plus (where the two lines cross) and how far the ends of the plus extend away from the centre (the same for the horizontal and vertical lines). You should also write a `draw.plus` function to provide a `draw` method. You should then be able to try drawing plusses. Once you have this working, you can write `rescale.plus` and `translate.plus` methods for objects of this class, and try them out. You should also be able to call the `smaller` function from the lecture with a `plus` object as its argument, without making any changes to `smaller`.

Finally, you can try to implement a new generic function for these objects, called `rotate90`, that rotates an object by 90 degrees counterclockwise. You may find it convenient to define a default method for this generic function (which would need to be called `rotate90.default`). For which classes of objects could you just let the default method be used? For which will you need to write a special method for `rotate90`?
